2026 IEEE NSS MIC RTSD

IEEE NPSS
NUCLEAR & PLASMA SCIENCES SOCIETY

Nuclear Science Symposium,
Medical Imaging Conference and
Room Temperature Semiconductor
Detector Conference

7 Nov – 14 Nov 2026

GRANADA, SPAIN

ABSTRACT SUBMISSION
DEADLINE: 12 MAY 2026

General Chair:	Stefan Ritt
Deputy Chair:	Juan M Górriz
NSS Chair:	Audrey Corbeil Therrien
NSS Deputy Chair:	Giulia Hull
MIC Chair:	Vesna Sossi
MIC Deputy Chair:	Roger Fulton
RTSD Co-Chair:	Michael Fiederle
RTSD Co-Chair:	Gerard Ariño

HYBRID

Welcome

Dear Colleagues,

We are delighted to announce that the upcoming onsite and hybrid IEEE Nuclear Science Symposium, Medical Imaging Conference, and Room Temperature Semiconductor Detectors Symposium will be held in **Granada, Spain, in November 7 – 14, 2026.** Nestled at the foot of the Sierra Nevada mountains in southern Spain, Granada is a city rich in history, culture, and natural beauty — a truly unique setting for our conference.

Granada is world-renowned for the **Alhambra**, a breathtaking Moorish palace and fortress complex that stands as one of Europe's greatest architectural treasures.

Pro tip: tickets often sell out weeks in advance, so if you want to visit — and you should — book at least a month ahead… seriously!

The city's distinctive blend of **Arab, Jewish, and Christian heritage** gives rise to a dynamic cultural atmosphere, visible in everything from its historic neighborhoods to its vibrant local cuisine and flamenco traditions. The modern **Palacio de Congresos** will serve as our venue, offering excellent facilities within walking distance of the historic city center. You will also find a wealth of museums, gardens, and scenic viewpoints nearby.

The technical program will be enriched by a diverse selection of **short courses** designed to strengthen the skills of early-career researchers and students, while also serving as valuable refreshers for experienced professionals. Further opportunities for engagement and development will be offered through **workshops and special events**, including Women in Engineering (WIE), Young Professionals (YP), and plenary sessions featured in the main program. The conference offers a hybrid option for people who cannot attend in-person, but those will miss the onsite Spanish flavor. We are confident that you will enjoy the warm Andalusian hospitality, outstanding gastronomy and the inspiring surroundings that Granada provides.

Yes, tapas come for free if you have a drink in most bars!

A spacious exhibition area will be available to connect with industry partners and fellow researchers in this culturally rich and welcoming city.

7 November, 2026

9:00 – 18:00 Alhamar @Hotel Saray Granada
SC-01 Front-End Electronics for Radiation Detectors

9:00 **SC-01-01**
Part I: Fundamentals
Gianluigi De Geronimo

11:00 **SC-01-02**
Morning Coffee

11:30 **SC-01-03**
Part II: Fundamentals
Gianluigi De Geronimo

13:30 **SC-01-04**
Lunch

14:30 **SC-01-05**
Part III: Fundamentals
Gianluigi De Geronimo

16:00 **SC-01-06**
Afternoon Coffee

16:30 **SC-01-07**
Part IV: Radiation Tolerance
Lodovico Ratti

9:00 – 18:00 Partal @Hotel Saray Granada
SC-02 Analog and digital SPAD-based photodetectors

9:00 **SC-02-01**
Part I: SPAD physics
Fabrice Retiere

11:00 **SC-02-02**
Morning Coffee

11:30 **SC-02-03**
Part II: Analog SiPMs, timing and read-out (metrology)
Stefan Gundacker

13:30 **SC-02-04**
Lunch

14:30 **SC-02-05**
Part III: Digital SiPMs: Introduction (quenching circuits, metrology)
Serge Charlebois

16:00 **SC-02-06**
Afternoon Coffee

16:30 **SC-02-07**
Part IV: Digital SiPMs: Architectures and Applications
Claudio Bruschini

17:30 **SC-02-08**
Part V: Demos

8 November, 2026

9:00 – 18:00 **Alhamar @Hotel Saray Granada**

16:30 **SC-05-07**
Part 4

9:00 – 18:00 **Partal @Hotel Saray Granada**
SC-06 **Medical predictions from imaging with machine learning: The implementation gap**

9:00 **SC-06-01**
Part I - Statistical testing for medical imaging

11:00 **SC-06-02**
Morning Coffee

11:30 **SC-06-03**
Part II - An introduction to Statistical Learning Theory

13:30 **SC-06-04**
Lunch

14:30 **SC-06-05**
Part III - The implementation gap

16:00 **SC-06-06**
Afternoon Coffee

16:30 **SC-06-07**
Part IV

10 November, 2026

9:00 – 18:00 **Alhamar @Hotel Saray Granada**
SC-07 **Medical Image Reconstruction: from Foundations to AI**

9:00 **SC-07-01**
Part 1 - Image reconstruction foundations

11:00 **SC-07-02**
Morning Coffee

11:30 **SC-07-03**
Part 2 - AI for image reconstruction: introduction

13:30 **SC-07-04**
Lunch

14:30 **SC-07-05**
Part 3 - Kernel and deep image prior methods

16:00 **SC-07-06**
Afternoon Coffee

16:30 **SC-07-07**
Part 4 - Generative AI for image reconstruction

9:00 – 18:00 **Partal @Hotel Saray Granada**
SC-08 **Fundamentals of Total-Body PET**

9:00 **SC-08-01**
Welcome and Introduction to Short Course
Ben Spencer, Steven Meikle, Georgios Angelis

9:15 **SC-08-02**
History and Motivation for Development of TB-PET
Ben Spencer

10:15 **SC-08-03**
Clinical and Research Applications of TB-PET
Steven Meikle

11:00 **SC-08-04**
Morning Coffee

11:30 **SC-08-05**
Performance of LAFOV PET Systems
Steven Meikle

12:20 **SC-08-06**
QC/QA of TB-PET Systems
Ben Spencer

13:10 **SC-08-07**
Pulse check Q & A
Steven Meikle, Ben Spencer, Georgios Angelis

13:30 **SC-08-08**
Lunch

14:30 **SC-08-09**
Acquisition Protocols for TB-PET
Ben Spencer

15:15 **SC-08-10**
Data Corrections for TB-PET
Georgios Angelis

16:00 **SC-08-11**
Afternoon Coffee

16:30 **SC-08-12**
Reconstruction for TB-PET
Georgios Angelis

17:15 **SC-08-13**
Data Analysis Tools for TB-PET
Steven Meikle

17:45 **SC-08-14**
Q & A and Course Review
Georgios Angelis, Steven Meikle, Ben Spencer

8 November, 2026

11:30 – 17:00 ANDALUCÍA II & III
WS-01 AI in Nuclear Sciences and Nuclear Medical Imaging – Review and future expectations (onsite only)

Chairs:
Jean-Baptiste Michaud (Sherbrooke)
Francis Loignon-Houle (Valencia)

11:30 **WS-01-01**
Kolmogorov-Arnold Networks: A New Paradigm for Explainable Prediction

11:45 **WS-01-02**
AI at the Front End: Machine Learning for Raw-Signal Processing in Semiconductor Detectors

15:53 - 16:15 - Break

16:14
16:15 - 17:00 - Invited Talk - Digital SPAD detectors: a broader perspective on trends and markets

16:15 **WS-02-11**
Packing Functionality under SPADs with nanometer scale 3D Stacking Technologies
Robert K. Henderson

17:00
17:00 - 17:30 - Coffee break

17:29
17:30 - 18:30 - Topic 2 - Vision

17:30 **WS-02-12**
ASPIDES: a digital SiPM in 110nm CMOS - rationale, technology choice and open challenges
Lodovico Ratti, On behalf of the ASPIDES collaboration

17:45 **WS-02-13**
PLATON - lessons learned on strategy and funding
Davide Sgalaberna

18:00 **WS-02-14**
SPADs in DRDs
Fabrice Retiere

18:15 **WS-02-15**
Digital SiPM initiatives in the USA
Shiva Abbaszadeh

18:29
18:30 - 18:45 - Topic 3 - Foundry perspective

18:30 **WS-02-16**
End-to-End SPAD Technology at Fraunhofer IMS
Jennifer Ruskowski

18:44
18:45 - 19:30 - Topic 4 - How could one size fits all - A panel and group discussion

18:45 **WS-02-17**
Discussion/debate: on collaboration and funding strategies to bring these technologies to use

19:30 **WS-02-18**
Summary and conclusions

19:35 **WS-02-19**
Cocktail

14 November, 2026

14:30 – 19:30 FEDERICO GARCÍA LORCA
WS-03 Total-Body Kinetic Modeling Workshop

14:30 **WS-03-01**
Welcome and Introduction
Negar Omidvari, Steven Meikle

14:39
14:40–15:40 - Session 1: Cutting Edge Methods in Total-Body Kinetic Modeling and Analysis
Richard Carson, Jing Wu

14:40 **WS-03-02**
Total-Body PET Kinetic Modeling: Challenges and Opportunities
Guobao Wang

15:00 **WS-03-03**
A pragmatic approach to ultrashort time-frame total-body PET image reconstruction
Andrew Reader

15:20 **WS-03-04**
Exploring inter-organ connectivity using static and dynamic whole-body PET
Irène Buvat

15:39
15:40–16:40 - Session 2: Emerging Frontiers
Negar Omidvari, Yun Zhao

15:40 **WS-03-05**
New hopes or old illusions? Image-derived input functions in the era of next-generation (brain) PET imaging
Tommaso Volpi

16:00 **WS-03-06**
High-Temporal Resolution PET Kinetic Modeling
Kevin Chung

16:20 **WS-03-07**
Whole-Body Functional [18F]FDG PET
Sharna Jamadar

16:40 **WS-03-08**
Coffee break

16:59
17:00–18:00 - Session 3: Industrial Perspectives – Translating TB-PET Kinetic Modeling into Practice
Negar Omidvari, Yun Zhao

17:00 **WS-03-09**
Enabling dynamic/parametric imaging applications in the era of ultra high sensitivity PET with Omni128
Elise Emond

17:15 **WS-03-10**
Practical Total-Body PET Kinetic Modeling with the Quadra
Paul Schleyer

17:30 **WS-03-11**
Practical Barriers, Innovative Solutions: Total-Body PET Kinetic Modeling for Research and Clinical Use
Qing Ye

17:45 **WS-03-12**
Short break

18:00 **WS-03-13**
18:00–19:00 - Session 4: SlicerDynamicPET Tutorial
Daniele Dall'Olio

19:00 **WS-03-14**
Drinks, Canapés, and Networking

15:00 – 19:00 MANUEL DE FALLA
WS-04 Emerging Directions in Theranostic Imaging: From PET and SPECT to Novel Modalities (onsite only)

Chairs:
Shiva Abbaszadeh (Santa Cruz)
Javier Caravaca (Berkeley)

15:00 **WS-04-01**
Radiotheranostics Beyond Boundaries: Hardware, AI, and the Future of Quantitative Imaging
Youngho Seo

15:15 **WS-04-02**
A Long Axial-FOV PET System with Embedded Spectroscopic Gamma-Cameras for In Vivo Imaging of Radiopharmaceutical Therapy
Ling-Jian Meng

15:30 **WS-04-03**
A High-Resolution Mobile Gamma-Camera for optimizing dosimetry in Molecular Radiotherapy : first clinical feasibility study for treatment of thyroid diseases with Radioactive Iodine
Laurent Menard

15:37 **WS-04-04**
The Personalized Remote Radiation Tracking Portable Organ Dosimetry Device
Robert S. Miyaoka

15:44 **WS-04-05**
Incorporating X-Ray and gamma-Ray Coincidence Detection for Improved Detection Efficiency and Image Quality in ^{177}Lu Imaging
Qingyang Wei

15:51 **WS-04-06**
Physics-Corrected List-Mode MLEM Reconstruction for Quantitative ^{177}Lu Cascade Gamma Coincidence Imaging
Hanshen Ye

15:58 **WS-04-07**
Learning Support Priors from ^{177}Lu with Projection-Domain Constraint for Quantitative ^{225}Ac SPECT Reconstruction
Zhengkun Dong

16:05 **WS-04-08**
Rapid Extended-Distance ^{177}Lu Imaging with a Portable Telephoto-Lens Magic-Cube Gamma Camera for Intra-Procedural Theranostic Assessment
Yuxi Zhang

16:12
Open Discussion I

16:40
Coffee Break

17:10 **WS-04-09**
Implementation of Radiation Detection Technologies, Quality Assurance, and Harmonized Control Standards for Theragnostic Programs in Emerging Healthcare Systems.
Ian M. Rossi

17:25 **WS-04-10**
New Horizons in Ultra-High Resolution 3D CZT Detectors and its impact on preclinical SPECT/PET
Alexander Cherlin

17:39 **WS-04-11**
A multimodal C-arm enabling concurrent X-ray and nuclear imaging for cost-effective theragnostic interventions
Dennis R. Schaart

17:46 **WS-04-12**
Theranostic SPECT with High Energy Resolution CZT Detectors
Peter G. Hotvedt

17:53 **WS-04-13**
Fast Timing for High-Energy Gammas with GAGG and BGO for Improved Theranostic
Fiammetta Pagano

18:00 **WS-04-14**
Event-Based Alpha- and Beta- Particle Imaging with iQID: From Quantitative Digital Autoradiography to Isotope Identification
Brian W. Miller

18:07 **WS-04-15**
How the next generation digital autoradiography can provide insight into theranostic bioequivalence
Stephen Adler

18:14 **WS-04-16**
Gamma-Positron Imaging and Event-Correlated Simulation for Emerging Theranostics
Matthew A. Kupinski

18:21 **WS-04-17**
Multiplexed PET for Theranostic Imaging
Joaquín López Herraiz

18:28
Open Discussion II

10 November, 2026

11:30 – 13:00 FEDERICO GARCÍA LORCA
JS-01 Joint Session NSS-MIC-RTSD

Chairs:
John Valentine (Berkeley)

11:30 **JS-01-01**
Uniformity, Stability and High-Flux X-ray Detection Performance of $FAPbBr_3$, $CsPbBr_3$ and CZT
Isabel Braddock

11:45 **JS-01-02**
Estimating requirements for scintillator-based photon counting detectors in CT
Scott Hsieh

12:00 **JS-01-03**
A four side buttable system in package for medical and industrial Photon-Counting CT
Torsten Solf

12:15 **JS-01-04**
A Vibrational-Scanning Single-Photon Emission Microscope (SPEM) for In Vivo 3-D Autoradiography of Targeted Alpha Therapy
Weijian Zhang

12:30 **JS-01-05**
Multi-Agent Pipeline with Local Large Language Models for Automated MCNP Script Review
Byoungil Jeon

12:45 **JS-01-06**
A Compact Educational Platform for Demonstrating TDAQ Concepts in Particle Detector Systems
Raffaele Giordano

15:00 – 17:05 FEDERICO GARCÍA LORCA
JS-02 Joint Session - NSS-MIC

Chairs:
Cinzia DaVia (Manchester)
Roger Lecomte (Sherbrooke)

15:00 **JS-02-01**
2026 IEEE TNS Best Paper Award

15:05 **JS-02-02**
Systematic Defect and Crystal-Field Engineering of LYSO-U Scintillators for Photon-Counting CT
Dongzhou Ding

15:20 **JS-02-03**
Energy resolved imaging with a fine-pitch YAGG-SiPM based indirect photon counting detector
Kenji Shimazoe

15:35 **JS-02-04**
Latest update on the glass-less TSV FBK SiPM for 2.5D integrated ToF-PET modules
Michele Penna

15:50 **JS-02-05**
The DIGILOG Project: μSiPM Sensor and Sub-20 ps Readout Electronics for ToF-PET
Samuele Bisi

16:05 **JS-02-06**
Real-Time DOI Layer Prediction in TOF-PET Detectors via FPGA Neural Network
Shuiting Xin

16:20 **JS-02-07**
Physics-Informed Deep Learning on FPGA for Inter-Crystal Scattering Correction in ToF-CT
Lamyae Jdid

16:35 **JS-02-08**
Cherenkov Photon Counting, Labeling, and Multi-Photon Timing Estimation for sub-100 ps CTR BGO TOF-PET Detectors
Joshua W. Cates

16:50 **JS-02-09**
3D-cylindrical microdetector arrays for microdosimetryin proton therapy
Consuelo Guardiola

17:30 – 19:00 FEDERICO GARCÍA LORCA
JS-03 Joint Session NSS-RTSD

Chairs:
Shariar Motakef (Natick)
Chiara Guazzoni (Milano)

17:30 **JS-03-01**
Role of Al_2O_3passivation on high-resolution 4H-SiC radiation detectors
Krishna C. Mandal

17:45 **JS-03-02**
Vacuum-deposited metal halide perovskite film as a radiation scintillator
Muzzamer Zahid

18:00 **JS-03-03**
FAST NEUTRON DETECTION USING A SINGLE-CRYSTAL DIAMOND DETECTOR
Bohumír Zaťko, Bohumír Zaťko

18:15 **JS-03-04**
Improving the spectral resolution of photons in silicon Timepix3 by correcting for the cluster size and by lowering the Krummenacher current
Jindrich Jelinek

18:30 **JS-03-05**
Simulation-based inference for uncertainty-aware interaction reconstruction in 3D CZT drift strip detectors
Alejandro Valverde Mahou

18:45 **JS-03-06**
One-Year Performance Analysis of the cadmium zinc TElluride Radiation Imager (TERI) in Orbit
Nicholas Kirschner

9 November, 2026

9:00 – 11:00 FEDERICO GARCÍA LORCA
NP-01 NSS Plenary Session

Chairs:
Audrey Corbeil Therrien (Sherbrooke)
Giulia Hull (Orsay)

9:00 **NP-01-01**
Welcoming remarks
Stefan Ritt

9:30 **NP-01-02**
The Shape of Light
Sara Cazzoli

10:20 **NP-01-03**
2026 Radiation Instrumentation Early Career Award (NSS)

10:30 **NP-01-04**
2026 IEEE Emilio Gatti Radiation Instrumentation Technical Achievement Award (NSS)

10:40 **NP-01-05**
2026 IEEE Glenn F. Knoll Radiation Instrumentation Outstanding Achievement Award (NSS)

11:30 – 12:30 FEDERICO GARCÍA LORCA
NP-02 NSS Plenary Session

Chairs:
Audrey Corbeil Therrien (Sherbrooke)
Giulia Hull (Orsay)

11:30 **NP-02-01**
Environmental sustainability in research
Hannah Wakeling

12:20 **NP-02-02**
2026 Valentin T. Jordanov Radiation Instrumentation Travel Grants and 2026 Paul Phelps Continuing Education Grant

12:25 **NP-02-03**
Introduction to lighning talks

12:30 – 13:00 FEDERICO GARCÍA LORCA
N-LT-01 NSS Lightning Talks 1

Chairs:
Audrey Corbeil Therrien (Sherbrooke)
Giulia Hull (Orsay)

12:30 **N-LT-01-01**
Facile, scalable and high-yield synthesis of zero-dimensional copper halide $Cs_3Cu_2Cl_5$ scintillator with near-unity quantum yield for high-resolution X-ray imaging applications
Byungha Shin

12:32 **N-LT-01-02**
Hydrophobic Solvent-Based Polishing for Performance Enhancement of Water-Sensitive Perovskite Scintillator Crystals
Seungho Song

12:34 **N-LT-01-03**
Organic Scintillator Light Yield Models for Sub-MeV Neutrons in EJ301D and d-stilbene
Christian A. Irvine

12:36 **N-LT-01-04**
Application of neutron sensitising layers to plastic scintillator
Matt P. Taggart

12:38 **N-LT-01-05**
Scintillation light quenching for energetic charged particles in GAGG:Ce
Felix Liang

12:40 **N-LT-01-06**
Temperature Dependence of Pulse Shape Discrimination in SiPM-Based EJ-276D Detectors
John Leland

12:42 **N-LT-01-07**
Performance evaluation of GaGG(Ce) scintillators with different photosensors
Miriam Caballero Rodríguez

12:44 **N-LT-01-08**
Combining cross-luminescent scintillators and µSiPMs for better timing in ToF-PET
Katrin Herweg

12:46 **N-LT-01-09**
Fast or Adapt: Proportional Gas in γ-ray Fields
David O'Connor

12:48 **N-LT-01-10**
Characterisation of edge-on fully-depleted monolithic CMOS silicon sensors
Matteo Barbagiovanni, On behalf of 1MICRON Collaboration

12:50 **N-LT-01-11**
Gain suppression study on LGADs with different gain layer designs
Leo Cavazzini

12:52 **N-LT-01-12**
Pulse-Shape-Based Slow-Rising Pulse Rejection for Reliable Charge-Carrier Transport Characterization in a Semiconductor Radiation Detector
Jihwan Boo

12:56 **N-LT-01-13**
Diagnosing Mechanisms for Charged Particle Attenuation Enhancement in Nanostructured Materials
Niko P. Speck

12:58 **N-LT-01-14**
Monolithic integration of cooling microchannels in all-silicon ladders for vertex detectors
Javier Fernández-Tejero

12:30 – 13:00 ALBÉNIZ & MACHUCA
N-LT-02 NSS Lightning Talks 2

12:30 **N-LT-02-01**
Ultra High-Rate Neutron Detection with ^{3}He Tubes via CF_4 Prompt Scintillation Readout
Luis M. Margato

12:32 **N-LT-02-02**
Characterization of 3D ultra-thin silicon-based thermal neutron detectors
Felipe Zamorano

12:34 **N-LT-02-03**
Scintillator Size Effects in Fiber-Based Neutron Detectors With Pulse-Shape Discrimination for BNCT
Hong-Da Liu, Hong-Da Liu

12:36 **N-LT-02-04**
Time-Resolved Imaging of Radioactive Gas with the 4π Gamma-Ray Imager C3G
Yoshiharu Kitayama

12:38 **N-LT-02-05**
Method for determining lithium ore's grade based on photoneutrons' lifetime measurement
Minfeng Yu

12:40 **N-LT-02-06**
Template-Matching Position Solving on FPGAs for a Thermal Neutron Detector
Matthew Loyd

12:42 **N-LT-02-07**
Localization of uranium samples in large cemented nuclear waste using active photon interrogation and a Bayesian inversion
Malo Lebreton, Malo Lebreton

12:44 **N-LT-02-08**
Hybrid Temperature Compensation and Radiation Damage Recovery with Scintillation Detectors
Dae yang Oh

12:46 **N-LT-02-09**
Simulations of A Novel Time-of-Flight β/γ Transmission Tomography Scanner
Robert Carmichael, Robert Carmichael

12:48 **N-LT-02-10**
Revealing Disorder Faster: Detector Upgrades for SANDALS-II
Sarah E. Mann, Sarah E. Mann

12:50 **N-LT-02-11**
Characterization and Radiation Damage Mitigation of Silicon Photomultipliers for Low Earth Orbit Applications
Shideh Davarpanah, On behalf of NUSES Collaboration

12:52 **N-LT-02-12**
Graphene Photodetectors for Vacuum-UV Through Visible Wavelengths
Alec Lindman

12:54 **N-LT-02-13**
FPGA-Based Real-Time SiPM Emulator with Sub-Nanosecond Temporal Quantization
Stefano Carsi

12:56 **N-LT-02-14**
Self-Powered Wireless Communication via Ambient Gamma-Ray Harvesting at Fukushima Daiichi
Takeshi Fujiwara

12:58 **N-LT-02-15**
Basic Development of a Wide-Field EUV Polarimeter for High-Energy Transient Sources
Soken Kuwabara

15:00 – 17:00 Poster Area
NSS-01 NSS Poster Session

Chairs:
Matteo Porro (Schenefeld)

15:00 **NSS-01-001**
Fast or Adapt: Proportional Gas in γ-ray Fields
David O'Connor

15:00 **NSS-01-003**
Development of a Monte Carlo Simulation–Based Analysis Technique for High-Pressure Ionization Chambers (HPIC)
Kyeong Hyeon Sung

15:00 **NSS-01-005**
High Granularity Readout Time Projection Chamber R&D for Future Circular e+e- Colliders
Huirong Qi, On behalf of Linear Collider Time Projection Chamber International Collaboration

15:00 **NSS-01-007**
A Semi-Analytical Method for Sensitivity Estimation of Parallel-Plate Boron-Coated

Ionization Chambers
Peng Tang

15:00 **NSS-01-009**
A New Efficient n-γ Pulse Shape Discrimination Technique for Fast Scintillation Detectors
Stefano Riboldi

15:00 **NSS-01-011**
Near infrared scintillation properties of rare earth doped fluorapatite transparent ceramics
Takayuki Yanagida

15:00 **NSS-01-013**
Hydrophobic Solvent-Based Polishing for Performance Enhancement of Water-Sensitive Perovskite Scintillator Crystals
Seungho Song

15:00 **NSS-01-015**
Combining cross-luminescent scintillators and µSiPMs for better timing in ToF-PET
Katrin Herweg

15:00 **NSS-01-017**
Temperature Dependence of Pulse Shape Discrimination in SiPM-Based EJ-276D Detectors
John Leland

15:00 **NSS-01-019**
Scintillation light quenching for energetic charged particles in GAGG:Ce
Felix Liang

15:00 **NSS-01-021**
Facile, scalable and high-yield synthesis of zero-dimensional copper halide $Cs_3Cu_2Cl_5$ scintillator with near-unity quantum yield for high-resolution X-ray imaging applications
Byungha Shin

15:00 **NSS-01-023**
Spectral-feature-based radionuclide and radiation-type discrimination using a plastic scintillation fiber detector for in-situ pipe measurements
Tomohisa Abe

15:00 **NSS-01-025**
Investigation of Coincidence Time Resolution in BaF_2:Y Scintillators for TOF PET

Applications
Junfeng Chen

15:00 **NSS-01-027**
Experimental Study of DOI Effects on the Timing Response of a 1”×2” LaBr3 Detector
Sara Gaitán Dominguez

15:00 **NSS-01-029**
Development of Mo-Doped Cs_2HfCl_6 for Dosimetry in High Dose-Rate Environment
Shinichiro Kondo

15:00 **NSS-01-031**
From $LaBr_3$:Ce to $Cs_2LiLa(Br,Cl)_6$:Ce Mixed-Halide Elpasolites: Tailoring Scintillation Response for High-Precision Gamma-Ray and Neutron Detection
Zhuochen Cai

15:00 **NSS-01-033**
Application of neutron sensitising layers to plastic scintillator
Matt P. Taggart

15:00 **NSS-01-035**
Micropower Generation and Radiation Detection with Cr-doped Al_2O_3 Transparent Ceramics
Noriaki Kawaguchi

15:00 **NSS-01-037**
Single-ended Multiplexed Readout Scintillation Detector With Depth of Interaction Capability: Architecture and Optical Simulation
Gabriela Jazvac

15:00 **NSS-01-039**
Performance evaluation of GaGG(Ce) scintillators with different photosensors
Miriam Caballero Rodríguez

15:00 **NSS-01-041**
Cosmic-Ray Muon Position Reconstruction via Dual-End Readout of Triangular Plastic Scintillators
Yaofeng Zhang

15:00 **NSS-01-043**
Scintillation Properties of ^{6}Li-doped CsI:Tl Crystals for Thermal Neutron Detection
Anil K. Gourishetty

15:00 **NSS-01-045**
Development of Plastic Scintillator by Thermal Polymerization for Gamma Spectroscopy
Anil K. Gourishetty

15:00 **NSS-01-047**
Comparative Analysis of Scintillators for TOF-DXA Detectors in the Low-Energy X-ray Region
Jiwon Nam

15:00 **NSS-01-049**
Improved Low-Energy Threshold Performance of a Vacuum-Compatible Hybrid Pixel Detector for Soft X-ray Applications
Yasukazu Nakaye

15:00 **NSS-01-053**
Development and Testing of the Strip Pairing Algorithm for the COSI Data Pipeline
Julian Gerber

15:00 **NSS-01-055**
Temperature-Dependent Charge Transport in Diamond Radiation Detectors
Owen A. Johnson

15:00 **NSS-01-057**
Monitoring neutron exposure in hyper-pure germanium detectors with in-situ capture reactions
Thomas Round

15:00 **NSS-01-059**
Pixel Architecture Effects on Neutron-Induced White Spot Generation in CMOS Image Sensors
Jihun Jeong

15:00 **NSS-01-061**
Characterisation of edge-on fully-depleted monolithic CMOS silicon sensors
Matteo Barbagiovanni, On behalf of 1MICRON Collaboration

15:00 **NSS-01-063**
Gain suppression study on LGADs with different gain layer designs
Leo Cavazzini

15:00 **NSS-01-065**
Pulse-Shape-Based Slow-Rising Pulse Rejection for Reliable Charge-Carrier Transport

Characterization in a Semiconductor Radiation Detector
Jihwan Boo

15:00 **NSS-01-067**
The Sensor, Packaging and INtegration (SPIN) group at Fondazione Bruno Kessler (FBK): capabilities, facilities and expertise
Pietro Tosato

15:00 **NSS-01-069**
High-voltage stress test and thermal recovery of an amorphous-silicon-passivated planar HPGe detector
LiHui Han

15:00 **NSS-01-071**
Development of a SiC-Based Muon Beam Monitor for the COMET Experiment
Kenya Okabe

15:00 **NSS-01-073**
Argon Ion-Assisted Polycrystalline PbO Layers for Direct-Conversion X-ray Imaging Detectors
Mikhail Vostokov

15:00 **NSS-01-075**
Quantum Dots-Based Short-Wave Infrared Avalanche Photodetectors
Xingzhan Wei

15:00 **NSS-01-077**
Characterization and Radiation Damage Mitigation of Silicon Photomultipliers for Low Earth Orbit Applications
Shideh Davarpanah, On behalf of NUSES Collaboration

15:00 **NSS-01-079**
Toward SiPM Single-Photon Detection Matrix using Ultrafast, Low Power RF Readout
Dominique F. Yvon

15:00 **NSS-01-081**
FPGA-Based Real-Time SiPM Emulator with Sub-Nanosecond Temporal Quantization
Stefano Carsi

15:00 **NSS-01-083**
Design and Single-Cell Verification of an Integrated Temperature-Compensation Architecture for Digital SiPMs in Extreme Environments
Jin-Seok Oh

15:00 **NSS-01-085**
Graphene Photodetectors for Vacuum-UV Through Visible Wavelengths
Alec Lindman

15:00 **NSS-01-087**
Development of a PLL-less 6.25Gbps Serializer and CML Transmitter for the LCLS-II Upgrade
Aseem Gupta

15:00 **NSS-01-089**
Performance Evaluation of Differential Amplifiers for Fast Scintillating Fiber Readout in Proton Therapy
Bayram Deniz

15:00 **NSS-01-091**

15:00 **NSS-01-093**
Design of the new Matterhorn detector for the 4th generation synchrotrons
Davide Mezza

15:00 **NSS-01-095**
A Low-Latency 28-nm CMOS ASIC for Superconducting Quantum Readout
Yunzhuo Zhang

15:00 **NSS-01-097**
Radiation Effects on COTS On-Board Computer and Boot/Data-Storage Media Configurations for Super-Low-Earth-Orbit Optical Satellites
Jongdae Sohn

15:00 **NSS-01-099**
A Versatile High Linearity Front-End Preamplifier with Wide Dynamic Range for Multiple SiPM Sensors
Jara García-Barrena, On behalf of NEXT collaboration

15:00 **NSS-01-101**
SPAGHETTI : An original instrument for the continuous gamma-ray based monitoring of hydrothermal volcanoes
Hervé Chanal

15:00 **NSS-01-103**
Evaluating AMD's Versal Architecture for Tapped Delay Line Time-to-Digital Converters.
Julien Rossignol

15:00 **NSS-01-105**
Probing Sub-20 ps Intrinsic Timing Limits of MVT-SiPM Readout for TOF-PET
Hui Lao

15:00 **NSS-01-109**
Design and characterization of a 28 nm CMOS asynchronous front-end for the readout of hybrid pixel sensors in future colliders
Luigi Gaioni

15:00 **NSS-01-111**
A 5.12-GS/s Time-Interleaved VCO-Based ADC With Digital Calibration for High-Speed Detector Waveform Digitization
Chenxi Chen

15:00 **NSS-01-113**
Development of an FPGA-based Hardware Data Injector for High-Energy Experiments
Marcel M. Boonen

15:00 **NSS-01-115**

15:00 **NSS-01-117**
MU-STAR-mini: A 5-GS/s Prototype Sampling Array for High-Resolution Multi-Channel Streaming Readout
Luca Macchiarulo

15:00 **NSS-01-119**
Implementation of FPGA-Based Time-to-Digital Converters with Zero Measurement Dead Time
Xinren Qi

15:00 **NSS-01-121**
A Pre-Study of a General-Purpose Trigger Processing Unit for the CEPC TDAQ System
Dong Liu

15:00 **NSS-01-123**
Design of the Ultra-Low-Power Readout Electronics for the Large Area ^{3}He Tube Array Detector at China Spallation Neutron Source
Weigang Yin

15:00 **NSS-01-125**
A modular, self-triggered firmware for the FPGA-based readout of electromagnetic

calorimeters at the INSIGHT@ELSA experiment
Benedikt Otto, On behalf of the INSIGHT collaboration

15:00 **NSS-01-127**
A Self-Triggered, Event-Driven Readout ASIC for the eXTP PFA X-ray Polarimeter
Ke Wang

15:00 **NSS-01-129**
Pulse shape discrimination by digital pulse processing
Felix Liang

15:00 **NSS-01-131**
Intrinsic time jitter of alternate data acquisition systems for the HISTARS project
Víctor Martínez Nouvilas

15:00 **NSS-01-133**
Feasibility Study of Analog Pulse Processing ASIC for SDD Array in High Count Rate XRF
Yuji Okubo

15:00 **NSS-01-135**
High-performance upgrade for Track Lab: processing Timepix4 hits efficiently at scale
Petr Mánek

15:00 **NSS-01-137**
A Scalable High-Throughput DAQ Architecture for Real-Time Proton Beam Monitoring Applications
Bayram Deniz, On Behalf of NOVO Collaboration

15:00 **NSS-01-139**
A Modular High-Bandwidth DAQ System for the Medipix4 ASIC Based on FPGA Ethernet Readout
Nicolò Vladi Biesuz

15:00 **NSS-01-141**
Measurement of Energy-Dependent Neutron-Induced Single-Event-Upset Rates for Multiple FPGA Types
Shunya Ueda

15:00 **NSS-01-143**
Wireless Dosimetry System for Interventional Radiology
Pedro M.M. Correia

15:00 **NSS-01-145**
FPGA firmware for ^{3}He resistive wire tube readout with CAEN R5560 ADC.
Davide Raspino

15:00 **NSS-01-147**
LDMX Silicon Tracker Data Acquisition System
Benjamin Reese

15:00 **NSS-01-149**
Latest Upgrades and Operation of the Neutron Veto Data Acquisition System for the XENONnT Experiment
Stefano Mastroianni, on behalf of the XENON Collaboration

15:00 **NSS-01-151**
Design and Integration of a Modular $LiInP_2Se_6$ Neutron Detector Prototype for Single-Crystal Diffractometry Applications
Mohamed El Amine Benkechkache

15:00 **NSS-01-153**
Improvement of Ambient dose equivalent rate Estimation for Airborne Radiation Monitoring Using Artificial Neural Networks with Vegetation and Topographic Information
Ayumu Miyahara

15:00 **NSS-01-155**
Explainable Radionuclide Identification Using FWHM-Aware Adaptive Banding in Gamma-Ray Spectroscopy
Seoyun Jang

15:00 **NSS-01-157**
Source-Transferable Machine Learning-based Pulse Shape Discrimination in 3D-Printed Plastic Scintillators
Anil K. Gourishetty

15:00 **NSS-01-159**
Spectro-Temporal Gamma-Ray Anomaly Detection with Context-Adaptive Background Modeling
Hannah Parrilla

15:00 **NSS-01-161**

15:00 **NSS-01-163**
Generative Overlay Augmentation for Robust Structural Region Segmentation in Dual-

Energy X-Ray Cargo Container Imagery
Yeon-Wook Kim

15:00 **NSS-01-165**
Development of Realistic Gamma-ray Spectrum Database Using Geant4 and U-Net-based Sim-to-Real Translation
Geon Kim

15:00 **NSS-01-167**
Real-Time Nuclide Identification via Physics-Region Preprocessing
Dongseong Shin

15:00 **NSS-01-169**
Development of a vehicle-mounted Directional radiation monitoring system using multiple NaI(Tl) detectors and an ANN algorithm
Hee Kyun Baek

15:00 **NSS-01-171**
Wavelet optimisation for improved photopeak extraction in low-count gamma-ray spectra
James Biggs

15:00 **NSS-01-173**
Real-Time Particle Hit Detection Using a 1D Convolutional Neural Network on a CAEN FPGA-Based Digitizer
Carlo Tintori

15:00 **NSS-01-175**
Development of an ANN-based Gamma-ray Spectrum Correction Algorithm for PVT Detectors
Jiwon Ra

15:00 **NSS-01-177**
measurement-guided x-ray image restoration using fourier stochastic differential equations
Seokwon Oh

15:00 **NSS-01-179**
A General-Purpose Radionuclide Identification Model for HPGe Gamma-Ray Spectrometry
Jim Zickefoose

15:00 **NSS-01-181**

15:00 **NSS-01-183**

15:00 **NSS-01-185**
High-Fidelity 3D MCNP Modeling for Waste Classification in PWRs
Changyeon Yoon

15:00 **NSS-01-187**
Six-Degree-of-Freedom Pose Estimation for Safety Monitoring in a Nuclear Glovebox
Lewis Mead

15:00 **NSS-01-189**
Photonuclear Processes in a Tungsten Matrix Collimator for Spatially Fractionated Radiation Therapy
Igor E. Anokhin

15:00 **NSS-01-191**
A Low-Energy X-ray Transmission Imaging Method for Detecting Metallic Microparticles in Single-Layer $LiFePO_4$ Batteries
Dehao Wang

15:00 **NSS-01-193**

15:00 **NSS-01-195**
Improved Scattering Modeling in CIVA-RT using a Next-Event Estimator
Sheraz Blas

15:00 **NSS-01-197**
Development of a spectral unmixing method for gamma-ray spectra analysis : application to airborne measurements
Luc Patryl

15:00 **NSS-01-199**

15:00 **NSS-01-201**
Hybrid Semantic–Keyword Analysis for the Classification of Nuclear Fuel Cycle Activities Using Open-Source Information
Yeon Woo Lee

15:00 **NSS-01-203**
Selective Use of Directionally Informative Non-Photopeak Events for Low-Count

Industrial Gamma Imaging
Linxin Lei

15:00 **NSS-01-205**
An Optical Surrogate Framework for Three-Dimensional Fusion Source Reconstruction
Zhong Zhang

15:00 **NSS-01-207**
Adaptive Tetrahedral Mesh Reconstruction for Industrial Computed Tomography
Junho Lee

15:00 **NSS-01-209**
Forward Simulation of High-Energy XPCI Using XRM-Derived Semiconductor Package Phantoms
Uijin Lee

15:00 **NSS-01-211**
Investigating Identifiability in Joint Transmission–Backscatter X-ray Image Registration with Energy-Dependent Source Geometry
Youngchol Choi

15:00 **NSS-01-213**
Development of a UAV-Mounted Radiation Survey System Integrating LaBr3(Ce) Detectors and LiDAR
Young-Yong Ji

15:00 **NSS-01-215**
Development of a Handheld Uranium Enrichment Analyzer Based on LaBr3 Detector and Relative Detection Efficiency Self-Calibration Method
Guorong Liu

15:00 **NSS-01-217**
Neutron Response Evaluation of Miniature Spherical Li-glass scintillators for Optical-Fiber-Based Detectors
Yutaro Saito

Basic Development of a Wide-Field EUV Polarimeter for High-Energy Transient Sources
Soken Kuwabara

15:00 **NSS-01-327**
Cryogenic and Underground Performance of the Diffuse BGO Scintillator Array in the KAPAE Phase II Detector
Dongwoo Jeong

15:00 **NSS-13-329**
Organic Scintillator Light Yield Models for Sub-MeV Neutrons in EJ301D and d-stilbene
Christian A. Irvine

17:30 – 19:00 FEDERICO GARCÍA LORCA

NSS-02 Neutron and gamma-ray detectors and applications, including security, dosimetry and other related applications

Chairs:
Abdallah LYOUSSI (Saint Paul-lez-Durance)
Malcolm J. Joyce (Lancaster)

17:30 **NSS-02-01**
Dead time and self-absorption corrections at high uranium grade for total count rate gamma probes
Bertrand Pérot

17:45 **NSS-02-02**
Identification and Reconstruction of Pair-Production Events in an Electron-Tracking Compton Camera via 3D Track Analysis
Taiyo Sato, Taiyo Sato

18:00 **NSS-02-03**
Design of a 2D neutron and gamma imager based on CPRE64
Chaoyang Zhao

18:15 **NSS-02-04**
Evaluation of a High-Efficiency Portable Compton-Imaging System for Radioactive Waste Characterization and Nuclear Decommissioning
Victor Babiano-Suárez

18:30 **NSS-02-05**
Development of a high-sensitivity portable gamma-ray imaging system for identifying radioactive material carriers
Goeun Lee

18:45 **NSS-02-06**
Development of a new gamma-ray spectrometer for measurements inside reservoirs
Yuki Morishita, Yuki Morishita

17:30 – 19:00 ALBÉNIZ & MACHUCA
NSS-03 NSS DAQ, front-end and electronics

Chairs:
Eric J. Mannel (Upton)

17:30 **NSS-03-01**
Dual Time-Over-Threshold Energy and PSD Readout of SiPMs Using FPGA-Based TDCs
Aaron Nowack

17:45 **NSS-03-02**
Development of Readout Electronics for a SiPM-Based Compton Camera
Alessio Brunamonti

18:00 **NSS-03-03**
High Count-Rate Modular Readout System for SiPM-Based Gamma-Ray Detectors
Martina Piroddi

18:15 **NSS-03-04**
High-Rate FPGA-Based Fully Digital SiPM Readout for Photon-Number-Resolving

Measurements in Quantum Optics and Quantum Communications
Stefano Carsi

18:30 **NSS-03-05**
Towards Multi-channel Direct Positron Emission Imaging using Cherenkov-Radiator-Integrated MCP-PMTs, FastIC+, and Time-to-Digital Converters in FPGA.
Julien Rossignol

18:45 **NSS-03-06**
TEMPOROC3 : A 64-channel SiPM read-out chip for time-of-flight measurement on monolithic crystal
Vsevolod Yeroshenko

17:30 – 19:00 PICASSO
NSS-04 Semiconductor detectors

Chairs:
Chiara Guazzoni (Milano)
Davide Mezza (Villigen)

17:30 **NSS-04-01**
Very-High-Energy Electron FLASH Radiotherapy at the PEER Beamline - Dosimetry and Biological Benchmarking
Dean Cutajar

17:45 **NSS-04-02**
New approach in 2D microdosimetry using Alpide pixelated detector
Dean Cutajar

18:00 **NSS-04-03**
AlphaBeast : A CMOS-based detector for real-time neutron production monitoring
Lucia Victoria Garcia Garcia

18:15 **NSS-04-04**
Comparative Performance Evaluation of pnCCD Sensor Variants with 36 µm Pixel Size
Šejla Hadžić, Šejla Hadžić

18:30 **NSS-04-05**
fine-pitch HPGe strip detectors for high-rate gamma-ray spectroscopy and imaging
Joanna M. Szornel

18:45 **NSS-04-06**
Repairing Proton Radiation Damage on n-type, Cross-Strip Germanium Detectors
Sophia E. Haight

10 November, 2026

9:00 – 11:00 FEDERICO GARCÍA LORCA
NSS-05 Neutron and gamma-ray detectors and applications, including security, dosimetry and other related applications

Chairs:
Anne-Sophie Lalleman (GIF SUR YVETTE)
Malcolm J. Joyce (Lancaster)

9:00 **NSS-05-01**
Time-of-Flight Neutron Imaging With a Segmented Organic Imager Cell
William Heriot, This work was supported in part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration, award number DE-NA0003920.

9:15 **NSS-05-02**
Development of an omnidirectional neutron imager with fractal geometry
Nishiki Matsubayashi

9:30 **NSS-05-03**
Neutron Spectroscopy Using a Spatially Resolved He-3 Slab Detector
Madeline L. Lockhart

9:45 **NSS-05-04**
Residual Interpulse 14-MeV Neutron Emission in Active Interrogation with Neutron Generators
Valentin Fondement

10:00 **NSS-05-05**
Neutron Flux Monitor (NFM): A Micromegas-Based Beam Monitor for the European Spallation Source
Ioannis Katsioulas

10:15 **NSS-05-06**
Development of a Handheld Fast Neutron Spectrometer Using Deuterated Scintillators and Spectrum Unfolding
Ariel A. Alcaide, Ariel A. Alcaide

10:30 **NSS-05-07**
Innovative neutron counting for high-rate double-differential cross-section in fragmentation events.
Iram B. Rivas Ortiz

10:45 **NSS-05-08**
First 3D-PDC Experimental Measurements of Fast Neutrons and PSD Performance
Amanda Steinhebel, Amanda Steinhebel

9:00 – 11:00 ALBÉNIZ & MACHUCA
NSS-06 Detector modeling and simulation

Chairs:
Shaun D. Clarke (Ann Arbor)
Angela Di Fulvio (Urbana)

9:00 **NSS-06-01**
ARES: A Web-Based Platform for Registration, Access, and Analysis of Radiation Simulation Results
Sacha E.R. Medaer

9:15 **NSS-06-02**
Monte Carlo simulation of a new Optical Neutron Detector geometry for generation-IV Sodium-cooled Fast Reactors
Valentin Gerenton, Valentin Gerenton

9:30 **NSS-06-03**
A Validated GEANT4 Model of a Dual-HPGe γ–γ Coincidence Spectrometer for Detection Sensitivity Evaluation
Thomas C. Stokes

9:45 **NSS-06-04**
Monte Carlo Quantum Imaging with Annihilation Photons
Ana Marija Kožuljević

10:00 **NSS-06-05**
Bringing Synchrotron X-ray Minibeam Radiotherapy into Clinical Relevance: Monte Carlo Validation of Clinically Relevant Treatment Fields at the Australian Synchrotron
Dean Cutajar

10:15 **NSS-06-06**
SimpleMC: A Simple and Flexible Monte Carlo Simulation Tool for Timepix Detectors
Chia-Wei Huang

10:30 **NSS-06-07**
Photodetector model for the ClearMind project: Toward ultra-high time resolution
Zoé Zobundzija

10:45 **NSS-06-08**
3-D simulation of carrier transport and signal formation in silicon detectors for charged particle identification
Andrea Castoldi

9:00 – 11:00 PICASSO
NSS-07 Scintillators

Chairs:
Etiennette Auffray (Geneva)
Shunsuke Kurosawa (Nagoya)

9:00 **NSS-07-01**
Crucible-Free Growth of High Melting Temperature Scintillators by the OCCC Method
Kei Kamada

9:15 **NSS-07-02**
$Cs_3Cu_2I_5$ Single Crystals Grown with Oleic- and Formic-Acid-Assisted Additives: Effects on Crystal Quality and Scintillation Properties
Bhavika Bansal

9:30 **NSS-07-03**
Novel $Cs_3Cu_2I_5$:Tl Scintillator Films for X-ray Imaging
Lakshmi Soundara Pandian

9:45 **NSS-07-04**
Growth and Pellet Fabrication of 2D Perovskite Scintillator Radiation Detectors
Amy J. Dickinson

10:00 **NSS-07-05**
Enhanced Light Outputs in Cs_2ZnCl_4 Single Crystals via Hydrothermal Purification and Cd Doping
Mingxue Deng

10:15 **NSS-07-06**
Scintillation Properties of Ce^{3+}-, Pr^{3+}-, and Eu^{2+}-Doped LiCl, LiBr, and LiI Single Crystals
Jarek Glodo

10:30 **NSS-07-07**
Characterising ZnSe(Al,O) for Real-Time Sr-90 Beta Spectroscopy
Arjana Kolnikaj

10:45 **NSS-07-08**
Exploring wavelength-shifting properties of nanocrystal layers and nanocomposites
Vojtech Zabloudil

15:00 – 17:00 ALBÉNIZ & MACHUCA
NSS-08 Synchrotron, FEL and XFEL detectors

Chairs:
Beatrice Pedretti (Milano)
Matteo Porro (Schenefeld)

15:00 **NSS-08-01**
Production Results of DEPFET-Based Modules for the DSSC Imager at the European XFEL
Stefano Maffessanti

15:15 **NSS-08-02**
Performance of the pFREYA16 ASIC for pixelated detectors in continuous-wave x-ray applications
Paolo Lazzaroni

15:30 **NSS-08-03**
DIANA: An LGAD-Based Architecture for Soft X-Ray Detection
Francesca Capocasa

15:45 **NSS-08-04**
Matterhorn: Initial Characterization of Single-Chip Assemblies
Viveka Gautam, On behalf of the detector group whose members include M. Anastasi, M. Bruckner, S. Ebner, S. Emiliani, K. Ferjaoui, D. Greiffenberg, S. Hasanaj, V. Hinger, V. Kedych, T. King, S. Li, C. Lopez-Cuenca, L. Lunin, A. Mazzoleni, S. Moses, A. Mozzanica, J. Mulvey, M. Muller, C. Ruder, B. Schmitt, S. Silletta, D. Thattil, X. Xie and J. Zhan

16:00 **NSS-08-05**
ORBIS: an X-ray SDD Array with Optimized Backscattering Detection Geometry
Pietro Barcella

16:15 **NSS-08-06**
Experimental Characterization of a Front-End Stage for Future XFEL Detectors
Adele Ciavarella-Ciavarella

16:30 **NSS-08-07**
Mapping of the charge collection function of hexagonal DEPFET pixels with the mesh experiment
Andrea Mason, Andrea Mason

16:45 **NSS-08-08**
Gated MCP High Resolution Detectors for UV, Soft X-ray photons, Ions, Neutrons and Electrons
Anton Tremsin

17:30 – 19:00 ALBÉNIZ & MACHUCA
NSS-09 Neutron and gamma-ray detectors and applications, including security, dosimetry and other related applications

Chairs:
Andrea Sagatova (Bratislava)
Lei R. Cao (Columbus)

17:30 **NSS-09-01**
Development and Experimental Validation of a Numerical Model for Fission Particles Multiplicity Counting using Polyvinyl Toluene Scintillators
Filip d'Almeida

17:45 **NSS-09-02**
Recent Advances in Developing Fluoride Eutectic Scintillators for Neutron Detection
Cai L. Wang

18:00 **NSS-09-03**
3D Boron-Coated Straw Detector Array for Tomographic Multiplicity Counting
Ming Fang

18:15 **NSS-09-04**
An Imaging and Spectroscopy Detector for High-Energy and High-Rate Gamma-Ray Measurements
Korbinian Urban

18:30 **NSS-09-05**
Ratiometric Alpha-Particle and Gamma-Ray Imaging with a Ligand-Stabilized $CsPbBr_3$Perovskite-Nanoparticle Coating on a 4.8-Megapixel Stacked CMOS Sensor
Viktor Gruev

18:45 **NSS-09-06**
Evolution of ZnS:Ag/^{6}LiF wavelength shifting fibre detectors from flat to tilted geometry
Giacomo Mauri

11 November, 2026

9:00 – 10:30 ALBÉNIZ & MACHUCA
NSS-10 Analog and Digital Circuits I

Chairs:
Giuseppe Bertuccio (Como)
Matteo Porro (Schenefeld)

9:00 **NSS-10-01**
NSX1: A 64-Channel Low-Power Front-End ASIC for Broadband Energy Silicon Drift Detectors Arrays
Gianluigi De Geronimo

9:15 **NSS-10-02**
Towards a 150 kHz Continuous Imager: The CoRDIA 0.5 Prototype 20 k Pixel Array
Ulrich Trunk

9:30 **NSS-10-03**
LID: A 10-GS/s Self-Triggered Readout IC for Tightly Coupled Strip and Pixel LGAD Arrays
Luca Macchiarulo

9:45 **NSS-10-04**
SparkPix-S: A Sparsified Readout Detector for 1 MHz Frame-Rate X-Ray Imaging - Design Progress and Early Characterization Results
Christos Bakalis

10:00 **NSS-10-05**
Global-ramp single-slope ADC with pixel-level comparison and built-in compression for large pixel arrays
Lodovico Ratti

10:15 **NSS-10-06**
Characterization of the Ignite64 ASIC in CMOS 28-nm technology for high time-resolution tracking
Luca Pacher, on behalf of IGNITE-Collaboration

9:00 – 10:30 MACHADO
NSS-11 AI and ML for radiation detection

Chairs:
Marco Carminati (Milano)

9:00 **NSS-11-01**
ML-based radiological clearance of activated metallic waste at CERN using synthetic data
Andrea Gomes

9:15 **NSS-11-02**
Inverse reconstruction of ^{137}Cs depth-dependent contamination in concrete from gamma spectrometry measurements
Antoine Hayek

9:30 **NSS-11-03**
Joint autoencoder-classifier network for particle-type identification in organic scintillator pulse pileup
Annamaria R. McHugh

9:45 **NSS-11-04**
Joint Neutron Source Localization and Identification using Machine-Learning-based Spectral Imaging
David Breitenmoser

10:00 **NSS-11-05**
Machine-Learning-Based Real-Time Gamma-Ray Direction Estimation Using Fractal Radiation Imaging Element
Miyuki Sasaki

10:15 **NSS-11-06**
Evaluating isotope identification methods for use with count-starved gamma spectra
James Biggs

9:00 – 11:00 **PICASSO**
NSS-12 **Novel detectors and associated technologies**

Chairs:
Christian Scharf (Berlin)
Miguel Ullan (Barcelona)

9:00 **NSS-12-01**
PLATON: a plenoptic single-photon camera with sub-nanosecond time resolution for particle detection through monolithic scintillating volumes
Davide Sgalaberna

9:15 **NSS-12-02**
A Capacitively Coupled GaAs SAM-APD with Cross-Delay Lines for Fully Digital 3D Hard X-ray Photon Imaging
Nicola Lusardi

9:30 **NSS-12-03**
Characterization of 4H-SiC implanted LGADs after 23 MeV Proton Irradiation
Arianna Morozzi

9:45 **NSS-12-04**
Status of GRAiNITA, a next generation calorimeter
Hervé Chanal

10:00 **NSS-12-05**
Small Dose Monitor based on Silicon Carbide diodes for FLASH radiotherapy
Celeste Fleta

10:15 **NSS-12-06**
Thin-Film and Single-Crystal Perovskite Detectors for Real-Time FLASH Radiotherapy
Mara Bruzzi

10:30 **NSS-12-07**
Particle-by-Particle Characterization of Clinical Carbon Ion Beams with a Silicon Strip Detector and High-Rate DAQ Systems
Felix Mas Milian

10:45 **NSS-12-08**
Diamond Quantum Sensor for High Fluence Neutron Detection
Raymond Cao

10:30 – 11:00 ALBÉNIZ & MACHUCA
N-LT-03 NSS Lightning Talks 3

Chairs:
Rejean Fontaine (Sherbrooke)

10:30 **N-LT-03-01**
Radiation-Hardened VCO in 28 nm FDSOI with Enhanced Frequency Stability Under Total Ionizing Dose
Muhammad Adeel Anwar, Muhammad Adeel Anwar

10:32 **N-LT-03-02**
Preamplifier Readout Electronics for Summing SiPMs Enhanced Circuit (PRESSEC) for Advanced SiPM Camera
Daniel David Marín

10:36 **N-LT-03-03**
Characterization of MAGIC: a SiPM Readout ASIC for Monolithic PET Detectors
Tommaso D'Incà, Tommaso D'Incà

10:38 **N-LT-03-04**
Photon Counting with FPGA Gigabit Transceivers: A Proof-of-Concept SiPM Readout for

TOF-PET
Marcos Turqueti

10:40 **N-LT-03-05**
Design and Implementation of an FPGA-Based Nuclear-Like Signal Generator
Yao Yang, Yao Yang

10:42 **N-LT-03-06**
High-performance preamplifier for spectroscopy systems based on High-Purity Germanium detectors
Fernando Ojeda, Fernando Ojeda

10:44 **N-LT-03-07**
Preliminary Test Results on Latest Version of FESA Readout ASIC for TOF-PET Detectors
Yuhao Yang

10:46 **N-LT-03-08**
Single-Shot Precision Decomposition of a 64-Channel FPGA TDC for TOF-PET
Giancarlo Sportelli

10:48 **N-LT-03-09**
SEU Evaluation of an Atom Switch-based FPGA for Slow-Control Systems
Kazuki Ueno

10:50 **N-LT-03-10**
MAPSSIC: Toward a Wireless Implantable Positron Probe for Molecular Neuroimaging of Awake and Freely Moving Rats
Mathieu Dupont

10:52 **N-LT-03-11**
Realistic Detector Response Model for COMET Phase-I Cylindrical Drift Chamber
Siyuan Sun

10:54 **N-LT-03-12**
Measurement and correction of high intensity effects on the pixel response of the DSSC DEPFET camera
Maurizio Ghisetti

10:56 **N-LT-03-13**
Towards a 64-Channel Monolithic SDD X-Ray Spectrometer for High-Throughput Synchrotron Applications
Beatrice Pedretti

10:58 **N-LT-03-14**
Education kit for radiation measurements
Masaharu Nomachi

10:30 – 11:00 MACHADO
N-LT-04 NSS Lightning Talks 4

Chairs:
Martin Grossmann (Villigen)
Trang Hoang (Ho Chi Minh)

10:30 **N-LT-04-01**
Recoil electron tracking in 3D CZT drift strip detectors: a feasibility study
Michał Kossakowski

10:32 **N-LT-04-02**
CVAE-Based Synthetic Thermoluminescence Silica Glass Jewellery Bead Glow Curve Generation
Lukasz Tomaszewski

10:34 **N-LT-04-03**
Characterizing Neutron Detection Efficiency in Timepix3: A Bayesian-Optimized FLUKA Approach
Sharmistha Mukhopadhyay

10:36 **N-LT-04-04**
Enhanced Spent Nuclear Fuel Characterization Using Sequential Detector Responses through Deep Learning
Beomkyu Kwon

10:38 **N-LT-04-05**
Robust Dual-Target Radioisotope Quantification Under Increasing Unseen Contaminant Complexity
Yeongjun Kim

10:40 **N-LT-04-06**
Automated Monte Carlo-Based Efficiency Transfer Integrated into HPGe Gamma Spectroscopy Workflows for High-Throughput Laboratories
Spencer Behling

10:42 **N-LT-04-07**
Neutron and secondary photon dose mapping of deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators via PHITS simulations
Andrea G. Alipio

10:44 **N-LT-04-08**
Bayesian Filtering Image Reconstruction for SourceLocalization and Tracking in Compton Imaging
John Leland

10:46 **N-LT-04-09**
Count-Level Effects on Radiomics Robustness and Harmonization in Total-Body PET Imaging
Mohamed Saber Azimi

10:48 **N-LT-04-10**
Development of a Single-Layer Dual-Ended Readout Compton Camera Prototype for Enhanced Spatial Imaging
Haoqi Wen

10:50 **N-LT-04-11**
Crystal Dual-Readout Calorimetry for Future e^+e^- Higgs Factories
Marcello Campajola

10:52 **N-LT-04-12**
Design of the ePIC Hadronic Barrel Calorimeter, Status of the Test stand and Prospects for Physics at the EIC.
Eric J. Mannel

10:54 **N-LT-04-13**
Off-detector Readout and Real-time Signal Processing for the ATLAS Liquid ArgonCalorimeter at the High-Luminosity LHC
Pablo Collado Soto, On behalf of the ATLAS Collaboration

10:56 **N-LT-04-14**
The LS3 Enhancement of the LHCb Electromagnetic Calorimeter
Eduardo Picatoste, on behalf of the LHCb ECAL Upgrade II RD Group

11:30 – 13:00 Poster Area
NSS-13 NSS Poster Session

Chairs:
Andrea Gonzalez Montoro (Valencia)

11:30 **NSS-13-002**
Gas Circulation and Pressure Protection System for the COMET Cylindrical Drift Chamber
Ryo Nagai

11:30 **NSS-13-004**
Performance of a 2D-THCOBRA Gaseous Detector with Ar/Xe Mixtures for X-Ray Imaging
Ana Luísa M. Silva

11:30 **NSS-13-006**
The effect of hole geometry on the ion-backflow of a single gas electron multiplier foil
Hussam Badran

11:30 **NSS-13-008**
Feasibility of a Compact Detector for LINAC Radioactivation Monitoring
Jeongho Kim

11:30 **NSS-13-010**
Temperature Dependence of Energy Resolution in a SiPM-Based Scintillation Detector for PET Applications
Solano Rigotti Caiano

11:30 **NSS-13-012**
Development of transparent ceramic Tl:NaI scintillators for gamma-ray detectors
Takayuki Yanagida

11:30 **NSS-13-014**
Simulation of Electron Escape within Thin Organic Scintillators
Ethan Schneider

11:30 **NSS-13-016**
Alignments of the Dual-Layer Flat-Panel Detectors and their Modulation Transfer Functions
Dong Sik Kim

11:30 **NSS-13-018**
Loading Surface-Modified $LiAlO_2$ Nanoparticles in Plastic Scintillators for Thermal Neutron Detection
Masanori Koshimizu

11:30 **NSS-13-020**
Development of Perovskite Quantum Dots with High Photoluminescence Quantum Yields and Their Loading in Plastic Scintillators
Masanori Koshimizu

11:30 **NSS-13-022**
Effect of geometry on the properties of 3D-printed scintillators
Anil K. Gourishetty

11:30 **NSS-13-024**
Development of a Gamma Camera for Real-Time Monitoring of High-Energy Gamma-Ray Environments
Youngjoo Park

11:30 **NSS-13-026**
Study on the Influence of Grain Size for the GAGG powder-PMMA composite scintillator Detector
Yantao Liu

11:30 **NSS-13-028**
Thermal Neutron Detection with Dy-doped LiF/CaF_2 Eutectic Composite
Noriaki Kawaguchi

11:30 **NSS-13-030**
Development of Afterglow and NIR Decay Curve Measurement Systems using a Field Emission-type Pulsed X-ray Source
Hiromi Kimura

11:30 **NSS-13-032**
One Dimensional TPE-4Br Supramolecular Scintillator for High-Speed X-ray Imaging
Xiaoqing Liu

11:30 **NSS-13-034**
Development of a Large-Area Diode-Multiplexed Scintillation Detector for Prompt Gamma Monitoring in Proton Therapy
Xiaodong Mo

11:30 **NSS-13-036**
Development of a Hand-Foot Monitor for Visualizing Alpha Contamination
Naoki Sagawa

11:30 **NSS-13-038**
Room-Temperature Synthesis of Na^+-Doped $Cs_3Cu_2I_5$ Single Crystals: Structural, Optical and Scintillation Properties
Anil K. Gourishetty

11:30 **NSS-13-040**
Thermal Cycling of Optical Coupling Material to Investigate Performance Degradation in Detectors
Zoe H. Sharpe

11:30 **NSS-13-042**

11:30 **NSS-13-044**
Performance of Improved CsI:Tl Coupled SiPM Detectors for Imaging Applications
Rastgo Hawrami, Rastgo Hawrami

11:30 **NSS-13-046**
Optical Control of Valence State in LuAG:Ce,Ca
Colleen Campbell

11:30 **NSS-13-048**
Study of elpasolite crystals for neutron/gamma spectroscopy : First measurements with CLYC:Ce
Isaac Zeghni

11:30 **NSS-13-050**
A feasibility study on CsPbBr3 perovskite crystals for time-of-flight PET
Chien-Min Kao

11:30 **NSS-13-052**
From Collision Cascades to Device Response: A Multiscale Study of Proton-Induced Defects in Silicon
Sarah Shoorian

11:30 **NSS-13-054**
DREAM : A miniaturized spectrometer for protons and electrons measurement in space
Arnaud Dufour

11:30 **NSS-13-056**
Bulk Stoichiometry and van der Waals Interface Engineering of CdTe for Room-Temperature X/γ-Ray Detectors
Qinghua Zhao

11:30 **NSS-13-058**
Alpha Particle Detection with sCMOS imager
Makoto Sasano

11:30 **NSS-13-060**
Development of Silicon Drift Detector Technology from Single-Element Devices to a 19-Pixel Module for X-ray Spectroscopy Applications
Ziyu Bao

11:30 **NSS-13-062**
Oxygen-Ion-Assisted Amorphous PbO Layers for Direct-Conversion X-ray Detectors
Galina Nagicheva

11:30 **NSS-13-064**
Custom Geometries for Broader Applications of the GAPS Si(Li) Detectors
Kelsey Yee

11:30 **NSS-13-066**
Neutron Measurements of ^{252}Cf in High-Gamma-Ray Environments Using Silicon Carbide (SiC) Semiconductor Detector
Kanta Nagai

11:30 **NSS-13-068**
Development of amorphous germanium blocking contact multi-electrode coaxial HPGe detectors for highcount-rate applications
Siyuan Yu

11:30 **NSS-13-070**
A Novel Compton-Polarimeter in Telescope Configuration for X-Ray Energies up to 1 MeV
Tobias Over-Winter

11:30 **NSS-13-072**
Benefits from the latest Clover and Custom Desgined HPGe Detector Technologies
Gabriela Ilie

11:30 **NSS-13-074**
An automated testing and characterization system for SiPM device arrays
Ciro Boiano

11:30 **NSS-13-076**
Construction and Testing of An In-Situ Magnetron Sputtering Plasma Monitoring Setup
Burak Bilki

11:30 **NSS-13-078**
Utilisation of the ISIS Digital Data Pipeline for Afterpulsing Analysis of PMT & SiPM Signals
Daniel E. Pooley

11:30 **NSS-13-080**
Dark Count Rate of LHCb Scintillating Fibre Tracker SiPMs as an In-Situ Radiation Monitor
Sacha E.R. Medaer

11:30 **NSS-13-082**
Radiation-Hardened CMOS-SPAD Design for Stable Geiger-Mode Operation
Doo-Hee Son

11:30 **NSS-13-084**
ClearMind: fast photo-detection for TOF-PET
Viatcheslav Sharyy

11:30 **NSS-13-086**
Characterization of High-Speed Photomultiplier Tubes with $LaBr_3$(Ce) scintillators
Miriam Caballero Rodríguez

11:30 **NSS-13-088**
TID irradiations of a Shunt-LDO designed in a 110 nm CMOS process for EPIC-SVT
Matthew Buckland

11:30 **NSS-13-090**
Characterization of Single-Event Upsets in a 90 nm Commercial Off-the-shelf SRAM caused by Low-Energy Protons
Shintaro Ishihara

11:30 **NSS-13-092**
Design and Implementation of an FPGA-Based Nuclear-Like Signal Generator
Yao Yang, Yao Yang

11:30 **NSS-13-094**
Radiation-Hardened VCO in 28 nm FDSOI with Enhanced Frequency Stability Under Total Ionizing Dose
Muhammad Adeel Anwar, Muhammad Adeel Anwar

11:30 **NSS-13-096**
A Radiation-Hardened R-2R Digital-to-Analog Converter with Branch-Local Diode-Replica Dummy Biasing
Duckhyun Kim

11:30 **NSS-13-098**
Preamplifier Readout Electronics for Summing SiPMs Enhanced Circuit (PRESSEC) for Advanced SiPM Camera
Daniel David Marín

11:30 **NSS-13-100**
Feasibility studies on readout topologies for a MHz-framerate continuous wave-mode X-

ray detector in 45nm SOI CMOS technology
Pradeep Kalavakuru

11:30 **NSS-13-102**
Characterization of MAGIC: a SiPM Readout ASIC for Monolithic PET Detectors
Tommaso D'Incà, Tommaso D'Incà

11:30 **NSS-13-104**
A Modular Warm Time-Division MultiplexedReadout Platform for SQUID Applications
Benjamin A. Reese

11:30 **NSS-13-106**
A Scalable Test Vehicle ASIC in 28-nm CMOS for Cryogenic Device Characterization
Panagiotis Zarkos

11:30 **NSS-13-108**
Intermediate-Dose Close-In Phase-Noise Instability in a 55-nm CMOS PLL Irradiated to 100 Mrad(Si)
Peng Zheng

11:30 **NSS-13-110**
A Low-Noise Multi-Channel Readout ASIC for High-Purity Germanium Detectors
Li He

11:30 **NSS-13-112**
A precision bandgap reference with improved noise performance for spectroscopy ASICs in 180 nm CMOS technology
Yinhe Zhu

11:30 **NSS-01-116**
Photon Counting with FPGA Gigabit Transceivers: A Proof-of-Concept SiPM Readout for TOF-PET
Marcos Turqueti

11:30 **NSS-13-118**
A 640 MHz Phase Locked Loop for High Energy Physics Environment in 28nm CMOS Bulk
Fabio D'Ottavi

11:30 **NSS-13-120**
Machine-Protection System for the PIP-II Linear Accelerator: Architecture and Data Processing Schemes
Jinyuan Wu

11:30 **NSS-13-122**
Comparison of discrete non-gated charge-to-time converters for SPECT application
Pauline Lafoux

11:30 **NSS-13-124**
150 Gbps data transfer Bay simulating Agata detector Readout
Nabil Karkour

11:30 **NSS-13-126**
Performance Testing and Characterization of CPRE12-64CZT: A Low-Noise 64-Channel Readout ASIC for 3-D Position-Sensitive CdZnTe Detectors
Long Wei

11:30 **NSS-13-128**
Fast timing performance of a front-end ASIC designed for high purity germanium strip detectors
Clio Sleator

11:30 **NSS-13-130**
A Fully FPGA-Based 3D (x–y–t) Imager with 24 µm Spatial Resolution for Cross Delay-Line Detectors
Nicola Lusardi

11:30 **NSS-13-132**
High-performance preamplifier for spectroscopy systems based on High-Purity Germanium detectors
Fernando Ojeda, Fernando Ojeda

11:30 **NSS-13-134**
MAPSSIC: Toward a Wireless Implantable Positron Probe for Molecular Neuroimaging of Awake and Freely Moving Rats
Mathieu Dupont

11:30 **NSS-13-136**
Single-Shot Precision Decomposition of a 64-Channel FPGA TDC for TOF-PET
Giancarlo Sportelli

11:30 **NSS-13-138**
Education kit for radiation measurements
Masaharu Nomachi

11:30 **NSS-13-140**
Preliminary Test Results on Latest Version of FESA Readout ASIC for TOF-PET Detectors
Yuhao Yang

11:30 **NSS-13-142**
SEU Evaluation of an Atom Switch-based FPGA for Slow-Control Systems
Kazuki Ueno

11:30 **NSS-13-144**
Validation and Integration of the COMET Phase-I Trigger System
Chihiro Yamada

11:30 **NSS-13-146**
Evaluation of a Charge Sharing Compensation with Synchrotron Radiation
Piotr G. Maj

11:30 **NSS-13-148**
A High-Precision and Wide-Dynamic Range Energy Acquisition Method based on MVT with Pulse-Shape for Elemental Logging
Huan Liu

11:30 **NSS-13-150**
Realistic Detector Response Model for COMET Phase-I Cylindrical Drift Chamber
Siyuan Sun

11:30 **NSS-13-152**
Improving UAV-Based Radiation Monitoring in Mountainous Forests Using ANN with Spectral Information
Kazuhiro Suzuki

11:30 **NSS-13-154**
Figure-Grounded Multimodal Retrieval-Augmented Generation for Radiation Equipment Manual Question-Answering
Minjong Kim

11:30 **NSS-13-156**
Physics Enhanced Machine Learning for Thermoluminescence Glow Curve Deconvolution
Lukasz Tomaszewski

11:30 **NSS-13-158**
A High-Fidelity Robotics Simulation Framework for Autonomous Radiation Source

Search
Lance M. Drouet

11:30 **NSS-13-160**
Robust Dual-Target Radioisotope Quantification Under Increasing Unseen Contaminant Complexity
Yeongjun Kim

11:30 **NSS-13-162**
Recoil electron tracking in 3D CZT drift strip detectors: a feasibility study
Michał Kossakowski

11:30 **NSS-13-164**
Enhanced Spent Nuclear Fuel Characterization Using Sequential Detector Responses through Deep Learning
Beomkyu Kwon

11:30 **NSS-13-166**
Development of a PINN-Based Defect Verification Algorithm for CANDU Spent Nuclear Fuel Bundles
Juwan Kang

11:30 **NSS-13-168**
Towards Spiking Neural Network-Inspired In-Pixel Processing for Radiation Detectors
Anna Kozioł

11:30 **NSS-13-170**
CVAE-Based Synthetic Thermoluminescence Silica Glass Jewellery Bead Glow Curve Generation
Lukasz Tomaszewski

11:30 **NSS-13-172**
Gamma-Ray Image Denoising and Source Enhancement Based on a Residual Convolutional Autoencoder
Jonghyun Park

11:30 **NSS-13-174**
Neural-Network Surrogate Modeling of TID-Induced Degradation in 180 nm Bulk NMOS Transistors
Minuk Seung

11:30 **NSS-13-176**
Deep Learning Positioning and Depth of Interaction Prediction with Automatic Gain

Mismatch Correction
Matthew Dilsizian

11:30 **NSS-13-178**
Deep learning for precise gamma-ray interaction in an hexagonal monolithic scintillation crystals for PET imaging
Lidia Jiménez Algarra

11:30 **NSS-13-180**
Characterizing Neutron Detection Efficiency in Timepix3: A Bayesian-Optimized FLUKA Approach
Sharmistha Mukhopadhyay

11:30 **NSS-13-182**
Background pattern recognition and its reconstruction during radiation shadowing by scanned vehicles in Radiation Portal Monitors.
Vladislav Kondrashov

11:30 **NSS-13-184**
Effect of Source Intensity Imbalance on Two-Point Angular Resolution in Coded-Aperture Imaging
Yuhang Qiu

11:30 **NSS-13-186**
X-Ray Measurement of Tubes Using Closed-Loop Residual-Driven Optimization Algorithm
Yuchang Sun

11:30 **NSS-13-188**
Verification of a Rapid Dose Assessment Program Against MCNP for Nuclear Power Plant Decommissioning
Changyeon Yoon

11:30 **NSS-13-190**
High-Reliability Tritium Monitoring Using Hardware Alpha Suppression and AI-Based Smoothing Filter
Sungho Lee

11:30 **NSS-13-192**
Automated Monte Carlo-Based Efficiency Transfer Integrated into HPGe Gamma Spectroscopy Workflows for High-Throughput Laboratories
Spencer Behling

11:30 **NSS-13-194**
Graph-Based Modeling of Organ and Lesion Radiomics Interactions in Theranostic SPECT/CT Imaging
Mohamed Saber Azimi

11:30 **NSS-13-196**
Quantitative Neutron Emission Tomography of Plutonium-Bearing Materials using a Boron-Coated Straw Detector Array
David Breitenmoser

11:30 **NSS-13-198**
Caesium 137 Radiation Transport Profile Modelling for Application to Physical and Simulation Environments
Emmanuel Leo

11:30 **NSS-13-200**
Bayesian Filtering Image Reconstruction for SourceLocalization and Tracking in Compton Imaging
John Leland

11:30 **NSS-13-202**
An Iterative Based Gain Calibration Method for Multi-Channel Readout Scintillation Detectors
Zijun Yan

11:30 **NSS-13-204**
A Python-based Tool for Automated Geant4 Simulations of Scintillation Detectors
Ayush Priyadarshi

11:30 **NSS-13-206**
Development and deployment of a compact beta/gamma spectrometry chain for autonomous ground vehicles in nuclear decommissioning
Pierre-Louis Antonsanti

11:30 **NSS-13-208**
Neutron and secondary photon dose mapping of deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators via PHITS simulations
Andrea G. Alipio

11:30 **NSS-13-210**
Count-Level Effects on Radiomics Robustness and Harmonization in Total-Body PET Imaging
Mohamed Saber Azimi

11:30 **NSS-13-212**
A Geant4 add-on package to emulate surface electron response in Monte-Carlo simulation
Georgios Konstantinou

11:30 **NSS-13-214**
Multi-energy Radiography Using a Three-energy Accelerator and Dual-layer Detectors
Zhusong Mei

11:30 **NSS-13-216**
Portable African Neutron-Gamma Laboratory for Innovative Nuclear Science
Pete Jones

11:30 **NSS-13-218**
Feasibility Study on Ghost Imaging-based Neutron Depth Profiling for 3D Lithium Distribution Mapping
Junhyeok Kim

11:30 **NSS-13-220**
Feasibility Study of Thermal-Neutron Localization Using a GAGG-Based Directional Probe
Yuhang Qiu

11:30 **NSS-13-222**
Empirical Test of Gamma Emission Tomography for Detecting Partial-defect within PWR-type Spent Nuclear Fuel
Hyung Joo Choi

11:30 **NSS-13-224**
Enrichment-Dependent Neutron Interrogation Spectrum Optimization for Delayed Neutron Temporal Measurement
Caryanne R. Wilson

11:30 **NSS-13-226**
Improving contraband thermal neutron capture gamma detection in low and medium-Z cargo with pulsed D-T active neutron interrogation
Ketaki Joshi

11:30 **NSS-13-228**
Detection of Water in Spent Nuclear Fuel by Prompt Gamma Activation Analysis
Brendan Green

11:30 **NSS-13-230**
Development of a Portable Alpha–Beta Detection Device for Decommissioning Sites
Yuki Morishita

11:30 **NSS-13-232**
Proof-of-Concept Pulsed Neutron Detection Using a Timestamping SOI Pixel Detector SOFIST3
Ayaki Takeda

11:30 **NSS-13-234**
Experimental and Simulation Studies of FFCC Measurements Using a D-D Neutron Generator
Makoto Maeda

11:30 **NSS-13-236**
Compact and modular ^{6}LiF:ZnS(Ag) neutron detectors
Felix Liang

11:30 **NSS-13-238**
Characterization of a Leak-Tight Radon Chamber for Exhalation Rate Measurements of NORM Products
Jin-Goo Kang

11:30 **NSS-13-240**
Compton Scattering Imaging for On-site Nondestructive Testing of Cultural Heritage
Xin Li

11:30 **NSS-13-242**
In Situ 300-m Depth Underwater Environmental Radiation Monitoring System with Cesium Preconcentration
Min Sun Lee

11:30 **NSS-13-244**
Vehicle Based Detection System for Gamma-Neutron Background Measurements
Luke G. Morris

11:30 **NSS-13-246**
Performance Evaluation of a Portable MMXRF for Safeguards Environmental Sample Analysis under Transport-induced Alignment Changes
Sung-Woo Kwak

11:30 **NSS-13-248**
Measurement of 3-dimentional Distribution of ^{60}Co in a Graphite Block by Three Pinhole

Gamma Cameras
Jun Kawarabayashi

11:30 **NSS-13-250**
Verification of the Outer Space Treaty with trapped Protons in the VanAllen Radiation belt
Areg Danagoulian

11:30 **NSS-13-252**
Optimization of Detector Configuration for Enhanced Neutron Imaging Reconstruction Accuracy in Tokamak Fusion Reactor
Gyeongjin Choi

11:30 **NSS-13-254**

11:30 **NSS-13-256**
Characterization of Floating Gate Dosimeter Structures through a Standardized FPGA-Based Radiation-Test Platform
Evgenia Leonida

11:30 **NSS-13-258**
Physics-Informed Response Matrix Optimization for Neutron Flux Unfolding
Kilyoung Ko

11:30 **NSS-13-260**
Comprehensive Modeling and Experimental Validation of a SiPM-Based Neutron–Gamma Pulse Shape Discrimination System
Orith Halfon

11:30 **NSS-13-262**
Blade Checker – Radioisotope-free Positron Generator coupled with HPGe-based Doppler Broadening Spectroscopy for aircraft components maintenance operation
Damian Ralet

11:30 **NSS-13-264**
Optimization of the neutron source size for compensated neutron well logging
Yu Xiang Liu

11:30 **NSS-13-266**
Three-Dimensional Radiation Source Reconstruction with a Compound-Eye Compton Camera Using a NeRF-Inspired Neural Field
Yongshun Xiao

11:30 **NSS-13-268**
Advancing Beam Diagnostics on ESS Neutron Beamlines: Simulation and Validation of Ionization Chamber Monitors
Evangelos Samouilidis

11:30 **NSS-13-270**
Indoor 3D Gamma Radiation Mapping Based on VSLAM and Its Application in NPPs
Hui Li

11:30 **NSS-13-272**
Photofission Prompt Neutron Measurements from Active Photon Interrogation of Depleted Uranium with a Superheated Droplet Detector
Johann Piekar

11:30 **NSS-13-274**
Characterization and Comparison of State-of-the-Art Handheld Gamma-Imaging Field Spectrometers
Ariel A. Alcaide

11:30 **NSS-13-276**

11:30 **NSS-13-278**
Prototyping ALPIDE-based Modules for the R^3B Target Recoil Tracker Detector
Matthew Buckland

11:30 **NSS-13-280**
Development of a Single-Layer Dual-Ended Readout Compton Camera Prototype for Enhanced Spatial Imaging
Haoqi Wen

11:30 **NSS-13-282**
A GRID CubeSat Phoswich Payload for Space-Based Neutron Lifetime Measurement
Qidong Wang, On behalf of GRID Collaboration

11:30 **NSS-13-284**
Crosstalk and Charge collection in the ATLASPix3.1
Sean Williams

11:30 **NSS-13-286**
Radiation-Tolerant Fast Analogue Pixel Test Structures in TPSCo 65 nm CMOS Technology for the ALICE ITS3 Upgrade
Umberto Savino

11:30 **NSS-13-288**
Off-detector Readout and Real-time Signal Processing for the ATLAS Liquid ArgonCalorimeter at the High-Luminosity LHC
Pablo Collado Soto, On behalf of the ATLAS Collaboration

11:30 **NSS-13-290**
Crystal Dual-Readout Calorimetry for Future e^+e^- Higgs Factories
Marcello Campajola

11:30 **NSS-13-292**
The LS3 Enhancement of the LHCb Electromagnetic Calorimeter
Eduardo Picatoste, on behalf of the LHCb ECAL Upgrade II RD Group

11:30 **NSS-13-294**
Design of the ePIC Hadronic Barrel Calorimeter, Status of the Test stand and Prospects for Physics at the EIC.
Eric J. Mannel

11:30 **NSS-13-296**

11:30 **NSS-13-298**
Operations and performance of a FD-MAPS Telescope based on the ARCADIA sensors
Piero Giubilato

11:30 **NSS-13-300**
Measurement and correction of high intensity effects on the pixel response of the DSSC DEPFET camera
Maurizio Ghisetti

11:30 **NSS-13-302**
XSTREAM Pathfinder: A Modular R&D Framework for Next-Generation High-Throughput X-ray Detectors at the European XFEL
Matteo Porro

11:30 **NSS-13-304**
Redesign of the DSSC IOB for Near- and Long-Term High-Rate Operation
Gabriele Fiumicelli

11:30 **NSS-13-306**
Towards a 64-Channel Monolithic SDD X-Ray Spectrometer for High-Throughput Synchrotron Applications
Beatrice Pedretti

11:30 **NSS-13-308**
Novel Alpha Spectrometer for Aqueous and Molten Salt Systems
Owen A. Johnson

11:30 **NSS-13-310**
The Beta Rhizotron: a Radioisotope Imaging System for Plant Biology Research
Andrew Weisenberger

11:30 **NSS-13-312**
True Random Number Generation for Post-Quantum Applications
Edward Cazalas

11:30 **NSS-13-314**

11:30 **NSS-13-316**
Optimization of working point for TES microcalorimetric gamma spectroscopy
Nolan I. Kowitt

11:30 **NSS-13-318**
Radiation Damage to Quantum Dots
Edward Cazalas

11:30 **NSS-13-320**
Simulation-based evaluation of a position-sensitive TES microcalorimeter for gamma-ray detection
Nao Hata

11:30 **NSS-13-322**
Architecture and Qualification of the GlowRIA radiation monitor: An Optical fibre based dosimeter compatible with Cubesat missions
Nourdine Kerboub

11:30 **NSS-13-324**
Scintillation imaging with Coded Aperture masks
Valentina Cicero

11:30 **NSS-13-326**
Application of a Compact Electrically Cooled HPGe Detector to Quality Control in Radiopharmaceutical Isotope Production
Gabriela Ilie

15:00 – 17:00 ALBÉNIZ & MACHUCA
NSS-14 Analog and digital circuits II

Chairs:
Gianluigi De Geronimo (Syosset)
Serge A. Charlebois

15:15 **NSS-14-01**
Graphene-Based Front-End Amplifier for Nuclear Instrumentation
Marcos Turqueti

15:00 **NSS-14-02**
ToRA : a 64-channel ASIC for the readout of gaseous detectors in a CMOS 65 nm technology
Giovanni Mazza

15:15 **NSS-14-03**
CHASER: A Charge Sensitive Amplifier and Sampling Circuit for CZT Detectors
Leonardo Bernardini

15:30 **NSS-14-04**
Design and Experimental Characterization of a 65 nm CMOS Readout Channel for the Si(Li) Tracker Upgrade of the GAPS Experiment
Luca Ghislotti

15:45 **NSS-14-05**
Measurements of HPSoCv3 - an integrated 9-channel 10 Gsps Waveform Digitizer for high density LGAD array
Luca Macchiarulo

16:00 **NSS-14-06**
Cryogenic MOSFET Modeling Applied to CSA Design for Germanium Detector Readout
Joel Georgeous

16:30 **NSS-14-07**
A Fully Charge-Pump-Based Powering Scheme for SDDs in 180 nm SOI Technology
Tobias Michel, Tobias Michel

16:45 **NSS-14-08**
Development and testing of the ASIX region: a low-noise 128-pixel building block with event-driven readout and on-chip A/D conversion
Massimo Minuti

15:00 – 17:00 MACHADO
NSS-15 Computational methods and data analysis

Chairs:
Martin Grossmann (Villigen)
Chulhee Min (Wonju)

15:00 **NSS-15-01**
Improving the Estimation Accuracy of the Inverse Estimation of the Radioactive Source Distribution at the Fukushima Daiichi Nuclear Power Station Using L2 Normalization
Dai Tateishi, Dai Tateishi

15:15 **NSS-15-02**
Template-Based Decomposition of Gamma Spectra for NORM Quantification
Fabio Davolio

15:30 **NSS-15-03**
Enhancing Low-Energy MVT Bi-exponential Convergence via Adaptive Initial Value Estimation
Guanning Su, Guanning Su

15:45 **NSS-15-04**
Dual-Modality Muon Imaging via Trigger Optimization and Image Fusion
Zhi Zhou

16:00 **NSS-15-05**
Effects of Inverse Compton Scattering Source Parameters on Output X-Ray Spectra for Medical Applications.
Henry Priestley

16:15 **NSS-15-06**
Latent-Space Modeling for Multi-Organ Radiomics Phenotyping in ^{177}Lu-Based SPECT/CT Imaging
Mohamed Saber Azimi, Mohamed Saber Azimi

15:00 – 17:00 PICASSO
NSS-16 Scintillators

Chairs:
Jarek Glodo

15:00 **NSS-16-01**
Asymmetry in time difference histograms for scintillators with different decay constants in coincidence
Akram Hamato

15:15 **NSS-16-02**
Ultrafast and Efficient 2D Perovskite Scintillators for Sub-50 ps TOF-PET and High-Resolution X-ray Imaging
Jiaqi Liu

15:30 **NSS-16-03**
Thick Optical-guiding Scintillator with Enhanced Crystal Quality for High-Resolution and High-Sensitivity X-ray Imaging
Yuhei Nakata

15:45 **NSS-16-04**
Development of 3D-Printable Plastic Scintillator Using Stereolithography for Radiation Detection Applications
Kunlanan Puprasit

16:00 **NSS-16-05**
Energy Spectroscopy Using Tin-Loaded Organic Glass Scintillators of Varying Sizes
Erin Neely

16:15 **NSS-16-06**
Position-Sensitive and Energy-Constrained Characterization of an Opaque Scintillation Detector
Sander Katz, On Behalf of the LiquidO Consortium

16:30 **NSS-16-07**
Large Scale Lu_2O_3:Yb Ceramics for High-Rate Calorimetry
Lakshmi Soundara Pandian

16:45 **NSS-16-08**
Calibration of the Light Detection System of the XEMIS2 Liquid Xenon Compton Camera
Yohann Ramsi

17:30 – 19:00 ALBÉNIZ & MACHUCA
NSS-17 DAQ, front-end and electronics

Chairs:
Eric J. Mannel (Upton)

17:30 **NSS-17-01**
A Configurable Dual-CDL Sigma-Delta Readout Circuit for Dual-Polarity and High-Precision Signal Detection in CsI: Tl SPECT
Xi Zhang

17:45 **NSS-17-02**
Design and Preliminary Characterization of a Waveform-Sampling ASIC-Based Readout System for the MASS-Cube CZT Detector
Chen Li

18:00 **NSS-17-03**
MALTA2 Sensor Characterization with a New Asynchronous Oversampling Readout
Fuat Kerem Işık

18:15 **NSS-17-04**
A fully-programmable mixed-signal RISC-V SoC for direct readout of radiation sensors
Valerio Pagliarino

18:30 **NSS-17-05**
The MIZAR ASIC: from mixed-signal design to the PBR mission
Andrea Di Salvo, On behalf of the JEM-EUSO Collaboration

18:45 **NSS-17-06**
A Timepix4-based High-Speed Imaging System for Energy-Resolved Neutron Imaging at CSNS
Yimie Yuan

17:30 – 19:00 MACHADO
NSS-18 Neutron and gamma-ray detectors and applications, including security, dosimetry and other related applications

Chairs:
Abdallah LYOUSSI (Saint Paul-lez-Durance)
Igor Jovanovic (Berkeley)

17:30 **NSS-18-01**
Fast Neutron Spectrometer for Fusion Diagnostics
Fabrice Retiere

17:45 **NSS-18-02**
Pixel Size-Induced Visibility Degradation and Its Mitigation for X-ray Dark-Field Baggage Scanners
Zhexin Wang

18:00 **NSS-18-03**
Three-Dimensional Isotopic Imaging via Portable Neutron Resonance Transmission Analysis
Kevin Sanchez

18:15 **NSS-18-04**
Neutron diffraction-contrast tomography demonstration using event-based Timepix camera
Anton Khaplanov

18:30 **NSS-18-05**
Associated-Particle Neutron Time-of-Flight Measurements of Curium-244 and Californium-252
Malcolm J. Joyce

18:45 **NSS-18-06**
Quantitative Contamination Mapping Using an Electron-Tracking Compton Camera for Nuclear Decommissioning
Shinya Sonoda

17:30 – 19:00 PICASSO
NSS-19 Nuclear, HEP and astrophysics detectors

Chairs:
Chiara Guazzoni (Milano)

17:30 **NSS-19-01**
Status of the Phase-2 Upgrade of the CMS Outer Tracker
Michael Tytgat, On behalf of the CMS Collaboration

17:45 **NSS-19-02**
Operation and Performance of the ATLAS Liquid Argon Calorimeter During LHC Run 3
Nick Fritzsche, On behalf of the ATLAS Collaboration

18:00 **NSS-19-03**
Building the TRISTAN Phase-1 Detector: Characterization of 1000 SDD Pixels
Marco Carminati, On behalf of KATRIN Collaboration

18:15 **NSS-19-04**
Detector Performance Results on the MOSAIX Stitched Sensor Structures for ALICE ITS3
Livia Terlizzi, On behalf of the ALICE Collaboration

18:30 **NSS-19-05**
The LHCb PicoCal: a New Radiation-hard ECAL with Picosecond Time Resolution
Eduardo Picatoste, on behalf of the LHCb ECAL Upgrade II R&D Group

18:45 **NSS-19-06**
digital SiPMs for future RICH detectors
Prabhleen Singh

12 November, 2026

9:00 – 11:00 ALBÉNIZ & MACHUCA
NSS-20 DAQ, front-end and electronics

Chairs:
David J. Abbott (Newport News)

9:00 **NSS-20-01**
Development and validation of the Forward Feature Extractor Prototype for high-speed data processing in the ATLAS L0Calo trigger systems
ATLAS Collaboration ATLAS Collaboration, On behalf of the ATLAS Collaboration

9:15 **NSS-20-02**
Lessons Learned from the sPHENIX Experiment
Martin L. Purschke

9:30 **NSS-20-03**
Architecture and Performance of a Versatile Trigger, Tracking and Readout System for Particle Detector Beam Tests
Liliana Congedo

9:45 **NSS-20-04**
TD-Link: A Daisy-Chain Optical Architecture for Integrated Data Readout and Deterministic Timing Distribution in Large-Scale Detector Systems
Andrea Abba

10:00 **NSS-20-05**
Design and test of a readout board for the ePIC dRICH detector
Davide Falchieri

10:15 **NSS-20-06**
Performance evaluation of SPIDER and ICECAL65 for the upgrade II of the LHCb calorimeter detector
Eduardo Picatoste, On behalf of the LHCb ECAL Upgrade II R&D Group

10:30 **NSS-20-07**
Design and Performance of the Fermilab Constant-Fraction Discriminator (FCFD) Readout ASIC for ePIC Barrel Time-of-Flight Detector
Datao Gong

10:45 **NSS-20-08**
LDMX Timing Distribution and Data AcquisitionSystem
Benjamin A. Reese

9:00 – 11:00 MACHADO
NSS-21 Photodetectors

Chairs:
Fabrice Retiere (Vancouver)
Stefan Gundacker (Vienna)

9:00 **NSS-21-01**
Development of a Cost-Effective PCCT Detector Based on Sub-Millimeter EQR SiPM and LYSO Array with High Count Rate and Adequate Energy Resolution
Yongqiang Yan

9:15 **NSS-21-02**
First Characterisation Results on Backside-Illuminated SiPM Prototypes from the IBIS Project
Roberto Preghenella, On behalf of the IBIS and IBIS_NEXT Collaborations

9:30 **NSS-21-03**
Photon-to-Digital Converters Enabling Event Classification Through Pulse Shape Discrimination
Serge A. Charlebois

9:45 **NSS-21-04**
Progress on Single-cell-access TSVs for 3D-integrated microSiPM readout in fast-timing SiPM detectors
Alberto Gola

10:00 **NSS-21-05**
PlatonSPAD: A Scalable Sensor for Elementary Particle Detection
Kodai Kaneyasu, Kodai Kaneyasu

10:15 **NSS-21-06**
Study of neutron irradiated CMOS SPADs for RICH detector applications
Rok Dolenec

10:30 **NSS-21-07**
Comparative Study of NIEL Effects on Dark Count Rate in 110 nm CMOS SPADs Under Neutron, Proton and Electron Irradiation
Marcello Campajola

10:45 **NSS-21-08**
First developments of NUV-DJ SiPM arrays forcryogenic operation for the LHCb SciFi tracker Upgrade II
Carina Antonia Trippl

9:00 – 11:00 PICASSO

NSS-22 Neutron and gamma-ray detectors and applications, including security, dosimetry and other related applications

Chairs:
Marek Flaska (University Park)
Bertrand Pérot (Saint-Paul-lez-Durance)

9:00 **NSS-22-01**
Learning Real-World Spectral Templates from a City-Scale Radiological Sensor Network
Hannah Parrilla

9:15 **NSS-22-02**
Spatially-derived Enhancement of Time-domain PSD and Spectroscopy Measurements
Patrick M. Collins-Price

9:30 **NSS-22-03**
Impact of Air Activation on Tritium Monitoring in Fusion Energy Systems
Shaun D. Clarke

9:45 **NSS-22-04**
Attention-Biased Additive Point Source Localization
Brian J. Quiter

10:00 **NSS-22-05**
VETTR: A Robotic Landmine Detection System via Associated Particle Imaging
Ryan Pavlovsky

10:15 **NSS-22-06**
Development of a Real-time Dose Rate Monitoring System Reading with Optical Fiber under the High-Dose Rate Condition
Shunsuke Kurosawa

11:30 – 13:00 ALBÉNIZ & MACHUCA

NSS-23 Analog and digital circuits III

Chairs:
Stefan Gundacker (Vienna)
Lodovico Ratti (Pavia)

11:45 **NSS-23-01**
A Timing ASIC for Large-area SiPM Readout with Channel Delay Compensation
Yi Fu

11:30 **NSS-23-02**
CMOS-Based QUBO Solver ASIC for Charged Particle Tracking
Hyunjoon Kim

12:00 **NSS-23-03**
Scalable FPGA-Based Dual-Threshold Time-Over-Threshold Readout Circuit for Fast-Component Discrimination in BaF_2
Min Hyeong Son

12:15 **NSS-23-04**
A Flexible Multi-Mode Digital Readout Architecture for High-Precision Low-Rate Time-of-Flight Detectors
Manuel Viqueira Rodriguez, On behalf of PetVision project

12:30 **NSS-23-05**
Analog Neural Network ASIC for In-Detector Processing: Experimental Validation of an Advanced Prototype
Michele Ronchi

12:45 **NSS-23-06**
ASIC Development of Rad-hard Embedded FPGA in 28nm for Machine Learning in Particle Detector
Aseem Gupta

11:30 – 13:00 MACHADO
NSS-24 Gas detectors

Chairs:
Michael Tytgat (Brussel)
Takeshi Fujiwara (Tskuba)

11:30 **NSS-24-01**
GEM detectors for the CMS muon system
Chiara Aimè, On behalf of CMS Collaboration

11:45 **NSS-24-02**
A new detector technology for the LHCb Muon system in the high luminosity era
Francesco Debernardis

12:00 **NSS-24-03**
A Straw Tube Chamber Prototype for the Inner Detector of a Future e^+e^- Collider Experiment
Julia Okfen

12:15 **NSS-24-04**
Characterisation of a Multitube detector for the CSPEC Cold Neutron Spectrometer
William Saenz-Arevalo

12:30 **NSS-24-05**
Characterization of a High-efficiency Multi Element Thick Gas Electron Multiplier Based Neutron Dosemeter
Haoshuai Wang

12:45 **NSS-24-06**
Xe-SF_6 mixtures for negative-ion detectors
Afonso P. Marques

11:30 – 13:00 PICASSO
NSS-25 Nuclear, HEP and astrophysics detectors

Chairs:
Hartmut Hillemans
Maurizio Ghisetti (Milano)

11:30 **NSS-25-01**
Early On-Orbit Characterization of the Neutron Radiation Detection Instrument-1B (NeRDI-1B)
Anthony L. Hutcheson

11:45 **NSS-25-02**
High-speed single-photoelectron detection for Cherenkov astronomy
Luca Giangrande

12:00 **NSS-25-03**
Experimental demonstration of thermal neutron effects and their suppression in a sampling-type veto detector
Toru Matsumura

12:15 **NSS-25-04**
A High-Performance Mid-Format SiC based Detection System for Radioactive Ion Beam Tagging and Diagnostics
Chiara Guazzoni

12:30 **NSS-25-05**
The General Antiparticle Spectrometer (GAPS) Instrument: Design, Performance, and First Antarctic Flight
Kelsey Yee, On behalf of the GAPS collaboration

12:45 **NSS-25-06**
The Future of In-Beam Gamma-ray Spectroscopy at RIBF: $CeBr_3$ Development for the HYPATIA Array
Luke Tetley, On behalf of the HYPATIA Collaboration

15:00 – 17:00 ALBÉNIZ & MACHUCA
NSS-26 AI and ML for radiation detection

Chairs:
Marco Carminati (Milano)

15:00 **NSS-26-01**
Emergent Physical Interpretability in Transformer Encoders for Radiation Anomaly Detection
Derian M. Mowen

15:15 **NSS-26-02**
Ground-Truth-Free Validation of Surface Radiation Mapping via Forward-Simulation Round-Trip
Byoung-Jik Kim

15:30 **NSS-26-03**
Backscattered Spectral Network Imaging Method Based on a Combined Long–ShortCrystal Detector
Junjun Li

15:45 **NSS-26-04**
A Machine Learning Approach to Inter-Crystal Scattering Kinematics for Multiple Emission Tomography
Luca Presotto

16:00 **NSS-26-05**
Real-Time Data Compression Using Machine Learning for the ARGO Dark Matter Detector
Sajedeh Esmaeilzadeh

16:15 **NSS-26-06**
Machine-Learning Based Rapid Characterization of HPGe Detectors Based on Full-Energy Peak Efficiency Responses
Kainan Zhang

16:30 **NSS-26-07**
Comprehensive Strategy for Track Signal Extraction in the COMET Phase-I Experiment using Deep Learning Algorithms
Joe Sato

16:45 **NSS-26-08**
Signal Electron Extraction and Energy Resolution the COMET Experiment
Yuya Kojima

15:00 – 17:00 MACHADO
NSS-27 Scintillators

Chairs:
Marco Pizzichemi (Geneva)
Lakshmi Soundara Pandian (Watertown)

15:00 **NSS-27-01**
Measurement of the Cross Section of $^{14}N(n, p)^{14}C$ Reaction Using Sample-Added Scintillator
Gengchen Li, Gengchen Li

15:15 **NSS-27-02**
Development of thermal neutron detector using co-doped Ce:$LaBr_3$/^{6}LiBr Eutectic Scintillators for High Gamma-Ray Backgrounds
Kei Kamada

15:30 **NSS-27-03**
Scintillators based on 2D perovskite single-crystals for the detection of rapid neutrons and gamma/neutron discrimination.
Fanny Thorimbert

15:45 **NSS-27-04**
Optimization of $Cs_2LiLa(Br,Cl)_6$:Ce Scintillation Crystals for Neutron Detection and n/γ Discrimination
Zhuochen Cai, Zhuochen Cai

16:00 **NSS-27-05**
Development of Tl and ^{6}Li Co-Doped $Cs_3Cu_2I_5$ for Remote Thermal Neutron Detection
Chihaya Fujiwara

16:15 **NSS-27-06**
Gamma-Neutron Detection with Intrinsic and Doped Ternary Halide Scintillators
Elsa Ariesanti

16:30 **NSS-27-07**
Neutron and Gamma Ray Pulse Shape Discrimination in Small, Fiber-Coupled Organic Glass Scintillators
Schuyler Tyler

16:45 **NSS-27-08**
Pulse Shape Discrimination in a 3D-Printable Perovskite–Polysiloxane Nanocomposite Scintillator
Matteo Polo

15:00 – 17:00 PICASSO
NSS-28 Semiconductor detectors

Chairs:
Shiva Abbaszadeh (Santa Cruz)
Lars R. Furenlid (Tucson)

15:00 **NSS-28-01**
Methylpiperazinium Perovskitoid for High-Performance X-Ray Detection
Hong Li

15:15 **NSS-28-02**
Design and Evaluation of Graphene Strip Arrays for Radiation Detection
Marcos Turqueti

15:30 **NSS-28-03**
Geometry-Defined Impact Ionization in Two-Stage Mesa-Type Silicon Electron Multipliers
Hironori Sonobe

15:45 **NSS-28-04**
Electrical and UHDR characterization of trench-isolated thin segmented silicon detectors
Diango M. Montalvan Olivares

16:00 **NSS-28-05**
Development and Electrical Performance Characterization of 3D Column-Trench Detector
Huimin Ji, Huimin Ji

16:15 **NSS-28-06**
Large-Area Silicon Pixel Sensor Processing on 8-Inch High-Resistivity Wafers
Juha Kalliopuska

16:30 **NSS-28-07**
Results from irradiated nLGAD sensors
Marco Ferrero

16:45 **NSS-28-08**
Insights into DC-coupled Resistive Silicon Detector (DC-RSD) results
Marco Ferrero

17:30 – 19:00 FEDERICO GARCÍA LORCA
NSS-29 NSS closing session and Student Paper Awards

Chairs:
Audrey Corbeil Therrien (Sherbrooke)
Giulia Hull (Orsay)

17:30 **NSS-29-01**
Summary of the conference

17:40 **NSS-29-02**
Student Paper Awards - Runner-Up Poster presentation

17:45 **NSS-29-03**
Runner-up Poster Presentation

17:50 **NSS-29-04**
Student Paper Awards - Winner Poster presentation

17:55 **NSS-29-05**
Winner Poster Presentation

18:00 **NSS-29-06**
Student Paper Awards - Runner-Up Oral Presentation

18:05 **NSS-29-07**
Runner-up Oral Presentation

18:20 **NSS-29-08**
Student Paper Awards - Winner Oral Presentation

18:25 **NSS-29-09**
Winner Oral Presentation

18:40 **NSS-29-10**
Closing and passing to NSS 2027

11 November, 2026

9:00 – 11:00 FEDERICO GARCÍA LORCA
MP-01 MIC Plenary Session 1

Chairs:
Vesna Sossi (Vancouver)
Roger Fulton (Sydney)

9:00 **MP-01-01**
Opening ceremony; General Chair and MIC welcome
Stefan Ritt, Vesna Sossi, Roger Fulton

9:15 **MP-01-02**
Marie Sklodowska-Curie Technical Field Award Introduction
Sara A. Pozzi

9:25 **MP-01-03**
Marie Sklodowska-Curie Technical Field Awardee Presentation | Decoding the Cancer Ecosystem Through Multiscale Imaging for Precision Medicine
Irene Buvat

10:10 **MP-01-04**
NPSS Richard F. Shea Distinguished Member Awardee Announcement
Steven R. Meikle

10:14 **MP-01-05**
NPSS Richard F. Shea Distinguished Member Presentation
Tba Tba

10:29 **MP-01-06**
Edward J. Hoffman Early Career Development Grant Introduction
Steven R. Meikle

10:31 **MP-01-07**
Edward J. Hoffman Early Career Development Grant Presentation
Tba Tba

10:41 **MP-01-08**
Ronald J. Jaszczak Graduate Award Introduction
Steven R. Meikle

10:42 **MP-01-09**
Ronald J. Jaszczak Graduate Award Presentation
Tba Tba

10:45 **MP-01-10**
Glenn F. Knoll Post Doctoral Educational Grant Introduction
Steven R. Meikle

10:46 **MP-01-11**
Glenn F. Knoll Post Doctoral Educational Grant Presentation
Tba Tba

10:49 **MP-01-12**
NPSS Glenn F. Knoll Graduate Educational Grant Introduction
Steven R. Meikle

10:50 **MP-01-13**
NPSS Glenn F. Knoll Graduate Educational Grant Presentation
Tba Tba

10:52 **MP-01-14**
NPSS Graduate Scholarship Award Introduction
Steven R. Meikle

10:53 **MP-01-15**
NPSS Graduate Scholarship Award Introduction Presentation
Steven R. Meikle

10:55 **MP-01-16**
Awardee Introductions: Jordanov Awards and Phelps Grants
Lorenzo Fabris

11:30 – 12:45 FEDERICO GARCÍA LORCA
MIC-01 Advanced tomographic reconstruction techniques (1)

Chairs:
Andrew J. Reader (London)

11:30 **MIC-01-01**
3D Diffusion Posterior Sampling with Patient-Specific PET Priors for Ultra-Low-Count SPECT in alpha therapy
Alejandro Lopez-Montes

11:45 **MIC-01-02**
Joint Reconstruction of Activity and Attenuation with Motion Estimation in PET using Diffusion Models
Clémentine Phung-Ngoc, Clémentine Phung-Ngoc

12:00 **MIC-01-03**
Flow Models for PET Image Reconstruction
George Webber

12:15 **MIC-01-04**
Flow Matching for PET Image Reconstruction
Fumio Hashimoto

12:30 **MIC-01-05**
Data-Driven Kernel EM Reconstruction Using Attention-Based Learning for Dynamic PET
Haoran Chang

11:30 – 12:45 MANUEL DE FALLA
MIC-02 High resolution imaging systems (organ-dedicated, small animal systems (1)

Chairs:
Tianyu Ma (Beijing)
Elena Maria Zannoni (Austin)

11:30 **MIC-02-01**
Development and Evaluation of Gym-PET for Functional Brain Imaging of Awake Running Mice
Xin Yu, Xin Yu

11:45 **MIC-02-02**
Preliminary Validation of Flexible On-Demand Customized Ultra-Resolution System for Targeted Performance Enhancement in Preclinical PET
Kexin Wang

12:00 **MIC-02-03**
Initial Performance Characterization of the SAVANT Ultra-High-Resolution Phoswich-Based DOI Brain PET Scanner
Roger Lecomte

12:15 **MIC-02-04**
A Physics-Guided Deep Learning Method for Fast System Matrix Modeling in Self-Collimating SPECT Using Sparse Point-Source Calibration
Qiqi Ye

12:30 **MIC-02-05**
BuckyPET: Performance Evaluation and NEMA Adaptation for Compact PET Geometries
David Perez-Benito

12:45 – 13:05 FEDERICO GARCÍA LORCA
M-LT-01 Advanced tomographic reconstruction techniques, X-ray imaging systems (CT, spectral CT, photo-counting CT)

Chairs:
Andrew J. Reader (London)

12:45 **M-LT-01-01**
SPECT Reconstruction via Diffusion Sampling from a PET Image Manifold for Theranostics
Huanzhe Wei

12:47 **M-LT-01-02**
Event-by-Event Energy-Dependent List-Mode Reconstruction for Quantitative ^{90}Y Bremsstrahlung SPECT
Chenyu Yan

12:49 **M-LT-01-03**
Introducing "T-Index"—A Metric for Quantifying Data Range and Sampling Sufficiency
Katsuyuki Taguchi

12:51 **M-LT-01-04**
Time-of-Flight X-ray Imaging with Scatter Rejection and Subtraction
Altea Lorenzon, Altea Lorenzon

12:53 **M-LT-01-05**
Robustness to Scatter in Dual Energy Bone Suppression for Chest Radiography
Wojciech Zbijewski

12:55 **M-LT-01-06**
Unrolled relaxed algorithm for 3D SPECT reconstruction
Corentin Constanza

12:57 **M-LT-01-07**
Three-Photon Bayesian Imaging of Ortho-Positronium
Wojciech Krzemien, On behalf of IMPET project

12:59 **M-LT-01-08**
Lutetium-176-Aided Joint Activity and Attenuation Reconstruction in TOF-PET Using Trust-Region Cubic Surrogate Optimization
Xin Zhao

13:01 **M-LT-01-09**
List-Mode Derived Synthetic Kernel-Based Image Reconstruction for Dynamic Total Body PET
Movindu Dassanayake

13:03 **M-LT-01-10**
Unsupervised micro-CT reconstruction from limited-angle and truncated data in cone-

beam geometry
Keisuke Izumitani

12:45 – 13:05 MANUEL DE FALLA
M-LT-02 High resolution imaging systems (organ-dedicated, small animal systems, X-ray imaging systems (CT, spectral CT, photo-counting CT), Quantitative imaging, image assessment and standardization

Chairs:
Tianyu Ma (Beijing)
Elena Maria Zannoni (Austin)

12:45 **M-LT-02-01**
Experimental Results from Novel Monolithic PET Detector and Application to Axillary Lymph Node Imaging
Timothy Cotroneo

12:47 **M-LT-02-02**
Spatial Characterization of PET Detectors Based on BGO Pseudo-slabs
Neus Cucarella

12:49 **M-LT-02-03**
SurfaceCam: A Close-Proximity Multi-Pinhole CZT Brain SPECT system with Enhanced Geometric Sensitivity and Spatial Resolution
Shubham Mandot

12:51 **M-LT-02-04**
In vivo Gold Nanoparticle Imaging in Mice for Tumor Detection Using SiPM-Based Photon-Counting CT
Shuma Midorikawa, Shuma Midorikawa

12:53 **M-LT-02-05**
Quantitative Evaluation of Liver Disease through Multi-modality Approach Combining SiPM-based PC-CT and MRI—Approach to the Visualization of Inflammation through Water Fraction Estimation —
Yu Furuta, On behalf of the joint research group of Kanazawa University, Waseda University, Ishikawa Prefectural University, and Proterial Ltd.

12:55 **M-LT-02-06**
Position-, direction- and contrast-dependent measurement of MLEM-reconstructed PET resolution using a 3D-printed cube
Santiago Alvarado Orozco

12:57 **M-LT-02-07**
A Clinically Viable, Scalable Implementation of Monte Carlo Scatter Correction for PET/CT
Michal Edelstein

12:59 **M-LT-02-08**
Evaluation of Motion Correction Methods on the NeuroEXPLORER Using Multi-Tracer Human Data
Jiazhen Zhang

13:01 **M-LT-02-09**
SSS Optimised for Monte Carlo Scatter Estimation for PET
Antonia Reeves

13:03 **M-LT-02-10**
Positron Range Confinement in Preclinical PET/MRI: A Multi-Isotope, Multi-Density Experimental Study
Andrea Gonzalez-Montoro, Andrea Gonzalez-Montoro

15:00 – 17:00 FEDERICO GARCÍA LORCA
MIC-03 X-ray imaging systems (CT, spectral CT, photo-counting CT)

Chairs:
Dimitra G. Darambara (London)
Katsuyuki Taguchi (Baltimore)

15:00 **MIC-03-01**
LUCID: Model-Free High-Rate Photon Counting
Paul Scoullar

15:15 **MIC-03-02**
Comparison of scintillator and semiconductor based photon counting detectors via a unique, modular, multi-level simulation framework (PC-SIM).
Oliver L.P. Pickford Scienti

15:30 **MIC-03-03**
Single Energy Material Decomposition via X-ray Grating Interferometry
Longchao Men

15:45 **MIC-03-04**
Performance Evaluation of Low-Dose 3D Small-Animal Imaging Using YSO/SiPM-Based Photon-Counting CT
Rui Zheng

16:00 **MIC-03-05**
Photon-Counting Spectral Dark-Field Micro-CT for Enhanced Tooth Microcrack Detection
Qianyue Ma

16:15 **MIC-03-06**
ePixUHR-100k: A 100 kfps Full-Frame Imager for the LCLS X-Ray FEL Upgrade
Aldo Pena-Perez

16:30 **MIC-03-07**
Inverse Analysis of Pulse Pile-Up and Charge Sharing in Photon-Counting Detectors
Rikuto Sawada

16:45 **MIC-03-08**
Towards the first ToF-CT X-ray image: acquisition and scatter correction
Gabriel Belanger

15:00 – 17:00 MANUEL DE FALLA
MIC-04 Quantitative imaging, image assessment and standardization

Chairs:
Christoph W. Lerche (Jülich)
Jorge Roser (Lübeck)

15:00 **MIC-04-01**
Single-Source Cross-Tracer Brain PET Attenuation Correction via Anchored Flow Matching with Attenuation Maps from Simultaneous Reconstruction
Min Jeong Cho

15:15 **MIC-04-02**
High-Energy Penetration Correction in Multi-Aperture SPECT Using Aperture–Plate Ray Decomposition
Yusheng Li

15:30 **MIC-04-03**
Improving Lutetium Background Radiation-based Attenuation Correction for CT-less PET Using Singles-derived Randoms
Bing Dai, Bing Dai

15:45 **MIC-04-04**
Estimation of random events in PET imaging using the time differences of uncorrelated singles
Maxime Toussaint

16:00 **MIC-04-05**
Quantitative Activities Evaluation of Ac-225 and Daughter Nuclides Using the Alpha-SPECT Mini System
Yong Du

16:15 **MIC-04-06**
Physics-Driven Methods for Standardizing Radiomics Features in CT Data
Joseph W. Stayman

16:30 **MIC-04-07**
Uncertainty estimation for ^{123}I-DaTSCAN
Kelley M. Ferreira

16:45 **MIC-04-08**
Towards Absolute Resolution Characterization in OSEM Reconstructed Images without Ground Truth: Using FBP Reconstructed Images as the Bridge
Yifan Hu

17:30 – 19:00 Poster Area
MIC-05 MIC Poster Session 1

Chairs:
Margaret E. Daube-Witherspoon (Philadelphia)
Fabian P. Schmidt (Tuebingen)

17:30 **MIC-05-001**
Variable Angle Slant-Hole Collimator for Molecular Breast Imaging System
Andrew Weisenberger

19:00 **MIC-05-004**
Characterization of the CHLOE readout for dual-ended BGO crystals for PET with the FastIC+
Claudio San Martín Valenzuela

20:30 **MIC-05-007**
A 0.32 mm Pitch GAGG Array-Based SPECT Detector
Junwei Du

22:00 **MIC-05-010**
Sub-millimeter PET detectors using multiplexed readout with ASIC
Zheng Liu

23:30 **MIC-05-013**
Performance Evaluation of a Position Sensitive SiPM for Decoding Ultra-Small Crystal

Arrays
Jianlang Hua

1:00 **MIC-05-016**
Joint Deconvolution Framework for Photon-Train Reconstruction from Dual-Channel SiPM Readouts
Minseok Yi

2:30 **MIC-05-019**
Pushing the CTR limits in thick dual-ended crystals readout with FastIC+
David Mazzanti

4:00 **MIC-05-022**
Deep Learning Depth-of-Interaction Estimation from Full-Waveform Single-Ended PET Readout: Spatial Resolution Limits
Luca Macchiarulo

5:30 **MIC-05-025**
Optical-Guiding Crystal Scintillator for Single-Cell Resolution Imaging
Fumihiko Nishikido

7:00 **MIC-05-028**
Crystal Topology and Channel Compression Optimization for a high-resolution Neuro PET/MRI TOF-DOI PET Detector
Thore Meyer

8:30 **MIC-05-031**
An ultralow-afterglow γ-camera prototype for hybrid interventional X-ray and scintigraphy imaging
Marc Snoeyink

10:00 **MIC-05-034**
CRYSP: towards an accessible TBPET
Laura Navarro-Cozcolluela, On behalf of the CRYSP group

11:30 **MIC-05-037**
Evaluation of a Low-Noise Ultra-Fast SiPM Time-of Flight Analog Readout Chip (LUSTAR)
Joshua W. Cates, Joshua W. Cates

13:00 **MIC-05-040**
A Dual-Ended Readout PET Detector Module With 0.75 mm Pitch LYSO Arrays for High-Resolution Small-Animal Imaging
Xianchao Huang

14:30 **MIC-05-043**
CNN-Based 2D Source Localization Using Collimator-Free Staggered Scintillator Arrays
Bryan Casanelli

16:00 **MIC-05-046**
Development and Experimental Characterization of a Fine-Pitch CZT SPECT Detector Head with Simulation-Guided Matched-Pixel Collimator Selection
Rui Wang

17:30 **MIC-05-049**
Monte Carlo simulations of positrons in uniform magnetic fields with PENELOPE
Héctor Alva-Sánchez

19:00 **MIC-05-052**
Impact of a Breast PET Insert on Lesion Detectability in Whole-Body PET/MRI
Hong Phuc Vo

20:30 **MIC-05-055**
Proposal of an L-shaped Dual-detector Multi-pinhole Myocardial SPECT System Using a CNN
Takumi Akatsuka

22:00 **MIC-05-058**
EduPETSIM: An Educational Web-Based Framework Integrating Simulation, Reconstruction, and Generative AI for Rapid Source Modeling
Trang Hoang, On behalf of EduPET Collaboration

23:30 **MIC-05-061**
Accelerating Monte Carlo Light Transport in Turbid Media with an Analytically Invertible Simplified Phase Function
Aristotelis-Nikolaos Rapsomanikis

1:00 **MIC-05-064**
Fast On-the-Fly System Matrix Computation for Broad-Energy Multi-Pinhole SPECT
Bo Gao

2:30 **MIC-05-067**
Monte Carlo Based Performance Evaluation of a Dual Panel PET&SPECT Trimodal Imager
Hang Yang

4:00 **MIC-05-070**
Experimental Validation and Calibration of a GATE Simulation Model for a Dedicated

Breast PET/MR Insert
Elnaz Olyaei

5:30 **MIC-05-073**
An Integrated Digital Twin Framework for Accurate Quantification of Preclinical Immuno-PET
Claudia Dominguez-Borrero

7:00 **MIC-05-076**
Tensor-Based Multi-Stage Evolution for Generative Design of Arbitrary Permanent Magnet Geometries for PET-compatible Low-Field MRI
Fumihiko Nishikido

8:30 **MIC-05-079**
Design of SSLE-PET with GATE Simulation Towards Sub-Second Dynamic Mouse Imaging
Han Gyu Kang

10:00 **MIC-05-082**
SPECT vs. Compton Camera for Prompt Gamma Monitoring in BNCT: a simulation study.
Tommaso Ferri

11:30 **MIC-05-085**
A Novel Inter-Crystal Scatter Positioning Method Using Variable-Bin Stochastic Conditional Probability Based on Energy and Depth-of-Interaction Ordering
Hyeongseok Shim

13:00 **MIC-05-088**
Validation of Compton camera simulations using GATE version 10 through experimental data
Zaina J. Hurani

14:30 **MIC-05-091**
Convertible Whole-Body Extension of a Brain-Dedicated Whole Gamma Imaging System:A Simulation Study
Go Akamatsu

16:00 **MIC-05-094**
Translating CLS Detector Technology from Brain to Whole-Body PET Imaging: A Simulation Study
Mizuki Furuta

17:30 **MIC-05-097**
Photon-Counting CT in the Context of Ultra-Low-Dose PET/CT
Samaneh Mostafapour

19:00 **MIC-05-100**
DMGR-Net: Dual-Modal Gated Residual Network for Lightweight PET/MRI Brain Parcellation
Minjie Wang

20:30 **MIC-05-103**
New Hyperion Detector Platform Electronics: Highly Integrated Mainboard, Tile Cable, and Sensor Tile
Bjoern Weissler

22:00 **MIC-05-106**
Development of a Shielded Digital PET Detector System for a Brain PET/MRI Insert
Oleksandr Bubon

23:30 **MIC-05-109**
Design and Performance Evaluation of a Full-Ring SPECT System Based on the Continuous LaBr3(Ce)
Kui Wang

1:00 **MIC-05-112**
Image quality assessment of a positron emission mammography prototype
Valeria Pérez-Martínez

2:30 **MIC-05-115**
Experimental Results from Novel Monolithic PET Detector and Application to Axillary Lymph Node Imaging
Timothy Cotroneo

4:00 **MIC-05-118**
Spatial Characterization of PET Detectors Based on BGO Pseudo-slabs
Neus Cucarella

5:30 **MIC-05-121**
Positron Range Confinement in Preclinical PET/MRI: A Multi-Isotope, Multi-Density Experimental Study
Andrea Gonzalez-Montoro, Andrea Gonzalez-Montoro

7:00 **MIC-05-124**
Resolution-Sensitivity Optimization with Expanded Position Maps in the CLS-7: A TOF-

DOI Brain PET System
Kurumi Narita

8:30 **MIC-05-127**
Performance evaluation of N-PET, a high-resolution TOF-DOI PET dedicated to brain imaging
Ming Niu

10:00 **MIC-05-130**
DOI-Dependent Energy Window for Reducing Lu Background in In-Beam SIRMIO PET
Munetaka Nitta

11:30 **MIC-05-133**
NEMA NU-2 performance tests of a prototype PET scanner using novel detectors capable of measuring the gamma interaction point in 3D
August Blomgren

13:00 **MIC-05-136**
SurfaceCam: A Close-Proximity Multi-Pinhole CZT Brain SPECT system with Enhanced Geometric Sensitivity and Spatial Resolution
Shubham Mandot

14:30 **MIC-05-139**
Local Activity and Uncertainty Quantification for Pre-clinical Compton Imaging of ^{213}Bi
Oscar H. Matousek

16:00 **MIC-05-142**
A Compact X-ray Dark-Field Imaging Setup and Corresponding Image Optimization
Xiaolei Yan

17:30 **MIC-05-145**
Digital phantoms that can reproduce diseases aiming for virtual radiation imaging experiments
Rina Nishigami, This is a collaborative study between Kanazawa University and Okayama University.

19:00 **MIC-05-148**
A novel computational scatter estimation method in CBCT with half ASG
Jiongtao Zhu

20:30 **MIC-05-151**
Quantitative Evaluation of Liver Disease through Multi-modality Approach Combining SiPM-based PC-CT and MRI—Approach to the Visualization of Inflammation through

Water Fraction Estimation —
Yu Furuta, On behalf of the joint research group of Kanazawa University, Waseda University, Ishikawa Prefectural University, and Proterial Ltd.

22:00 **MIC-05-154**
Introducing “T-Index”—A Metric for Quantifying Data Range and Sampling Sufficiency
Katsuyuki Taguchi

23:30 **MIC-05-157**
In vivo Gold Nanoparticle Imaging in Mice for Tumor Detection Using SiPM-Based Photon-Counting CT
Shuma Midorikawa, Shuma Midorikawa

1:00 **MIC-05-160**
End-to-End Simultaneous Combined Scatter Correction and Metal Projection Segmentation for CBCT Metal Artifact Reduction Network
Junjie Zhou

2:30 **MIC-05-163**
X-ray Scattering in Dual-Layer Flat-Panel Detectors
Dong Sik Kim

4:00 **MIC-05-166**
Development and Experimental Validation of a Low-Cost Benchtop Micro-CT System
Pedro M.M. Correia

5:30 **MIC-05-169**
Development of a Robot-Arm-Based Automated Transmission and Backscatter X-ray Image Acquisition System for AI Training Data Generation
JeongHee Lee

7:00 **MIC-05-172**
Robustness to Scatter in Dual Energy Bone Suppression for Chest Radiography
Wojciech Zbijewski

8:30 **MIC-05-175**
Time-of-Flight X-ray Imaging with Scatter Rejection and Subtraction
Altea Lorenzon, Altea Lorenzon

10:00 **MIC-05-178**
Iodine Sensitivity in Photon Counting CT Using Conventional and Diffusion-Based Material Decomposition Algorithms
Grace J. Gang

11:30 **MIC-05-181**
TCMnet: An Automatic Tube Current Modulation Policy Based on Neural Network
Haoyu Zhang

13:00 **MIC-05-184**
A Fully Quantitative Reconstruction Framework Tailored for Depth-of-Interaction PET Systems
Yihao Chen

14:30 **MIC-05-187**
Unsupervised micro-CT reconstruction from limited-angle and truncated data in cone-beam geometry
Keisuke Izumitani

16:00 **MIC-05-190**
A Self-Supervised Framework for Simultaneous Reconstruction of Activity and Attenuation in TOF-PET
Hao Jia

17:30 **MIC-05-193**
Extended Field-of-View Reconstruction for Full-Ring Multi-Pinhole SPECT
Qiao Liu

19:00 **MIC-05-196**
CT Image Reconstruction Using Deep Image Prior with VoxelMorph
Kensuke Hori

20:30 **MIC-05-199**
A Boosting Diffusion Model for Ultra-Sparse-View CT reconstruction
Yura Kimura

22:00 **MIC-05-202**
SPECT Reconstruction via Diffusion Sampling from a PET Image Manifold for Theranostics
Huanzhe Wei

23:30 **MIC-05-205**
Plug-and-Play PET Image Reconstruction Using Diffusion Models
Tomoya Minagawa

1:00 **MIC-05-208**
List-Mode Reconstruction for Gamma-Positron Imaging
Matthew A. Kupinski

2:30 **MIC-05-211**
Pilot Clinical Evaluation of CT-Less PET Attenuation Correction Using Back-Scatter Coincidences on the NeuroEXPLORER System
Zhongzhi Liu

4:00 **MIC-05-214**
Unrolled relaxed algorithm for 3D SPECT reconstruction
Corentin Constanza

5:30 **MIC-05-217**
Multiple Emission Tomography: GPU-Accelerated LM-OSEM Reconstruction for Compton Events
Matteo N. Colombo

7:00 **MIC-05-220**
List-Mode Derived Synthetic Kernel-Based Image Reconstruction for Dynamic Total Body PET
Movindu Dassanayake

8:30 **MIC-05-223**
Three-Photon Bayesian Imaging of Ortho-Positronium
Wojciech Krzemien, On behalf of IMPET project

10:00 **MIC-05-226**
Event-by-Event Energy-Dependent List-Mode Reconstruction for Quantitative ^{90}Y Bremsstrahlung SPECT
Chenyu Yan

11:30 **MIC-05-229**
Evaluation of Cash C as a Cost Function for xSPECT Conjugate Gradient
Francesc Massanes

13:00 **MIC-05-232**
Investigation of Ray Driven Collimator Detector Response Model for Multi-Photopeak SPECT Reconstruction
Thibaut Merlin

14:30 **MIC-05-235**
Deep Kernel Gaussian Process Prior for Robust, Anatomically Guided Radiation Image Reconstruction
Jaewon Lee

16:00 MIC-05-238
ChameleonIQ: Bridging NEMA NU-2 and NU-4 Standards through Automated Image Analysis
Edwing Y. Ulin-Briseño

17:30 MIC-05-241
Position-, direction- and contrast-dependent measurement of MLEM-reconstructed PET resolution using a 3D-printed cube
Santiago Alvarado Orozco

19:00 MIC-05-244
Evaluation of Motion Correction Methods on the NeuroEXPLORER Using Multi-Tracer Human Data
Jiazhen Zhang

20:30 MIC-05-247
A Clinically Viable, Scalable Implementation of Monte Carlo Scatter Correction for PET/CT
Michal Edelstein

22:00 MIC-05-250
Down-Scatter Correction for PET-induced contamination in simultaneous PET&SPECT imaging
Hengyi Li

23:30 MIC-05-253
A Quantitative Reconstruction Framework for Variable-Pitch Multi-Layer DOI Brain PET
Yihao Chen

1:00 MIC-05-256
Intra-frame motion correction for dynamic PET using mutual information-based registration
Simon Noë

2:30 MIC-05-259
Head Motion Correction Improves Machine Learning Classification of Alzheimer's Disease from PET
Eléonore V. Lieffrig

4:00 MIC-05-262
CT-less Data Corrections For Dedicated Cardiac PET Scanners
Florence M. Muller

5:30 **MIC-05-265**
AmyPET: A Comprehensive Automated Framework for Static and Dynamic NeuroPET Quantification
Pawel J. Markiewicz

7:00 **MIC-05-268**
SSS Optimised for Monte Carlo Scatter Estimation for PET
Antonia Reeves

8:30 **MIC-05-271**
Quantitative Activities Evaluation of Ac-225 and Daughter Nuclides Using the Alpha-SPECT Mini System
Yong Du

10:00 **MIC-05-274**
Exploring a Novel Timing Calibration Approach for a Brain-Dedicated Time-of-Flight PET Scanner
James D. Ho

11:30 **MIC-05-277**
Preliminary Study on Thick-Slab Image Generation of Digital Breast Tomosynthesis
Subong Hyun

13:00 **MIC-05-280**
Torch-Enabled STIR: Validation on CPU and GPU
Nikos Efthimiou

14:30 **MIC-05-283**
Post-Reconstruction Spill-In Correction Methods in Lung PET Under Heterogeneous Conditions
Claire J. Brooks

16:00 **MIC-05-286**
Data-Driven Motion Artifact Correction for Wearable PET
Qiyu Peng

17:30 **MIC-05-289**
Radiographic Scatter Correction via Pixelwise Alpha Blending of Dark and Bright Channel Priors
Sanghyun Cho

19:00 **MIC-05-292**
Adapting Timepix4 single-particle trackinginstrumentation for medical X-ray imaging
Petr Mánek

20:30 **MIC-05-295**
A phase shifting method to provode three dimensional position information of an incident gamma ray
Shuwei Zhao

22:00 **MIC-05-298**
Simultaneous Dose Reduction and Resolution Recovery in Preclinical SPECT via Deep Learning
Elise Taragola

23:30 **MIC-05-301**
Self-supervised PET Denoising Based on the Noise2Noise Principle
Sacha Bouchez-Delotte

1:00 **MIC-05-304**
Python Integration in CASToR: Application to the End-to-End DIP-Based PET Reconstruction
Nasrin Taheri

2:30 **MIC-05-307**
DOI Calibration and Resolution Estimation in PET Detector Panels Using Uncollimated Irradiations
Francisco E. Enriquez-Mier-y-Teran

4:00 **MIC-05-310**
Virtual Imaging Trial to Evaluate the Impact of Acquisition Protocols on Harmonized Radiomic features in multi-site PDAC CT
Debojyoti Pal

5:30 **MIC-05-313**
Allometric Scaling of PSMA Uptake as a Novel Biomarker for Predicting Biochemical Response in Prostate Cancer
Fereshteh Yousefirizi

7:00 **MIC-05-316**
A Cucker–Smale Flocking Model for Edge-Aware Medical Image Analysis
Amirreza Hashemi

8:30 **MIC-05-319**
ComBat-Driven Latent Representation Learning for Robust Multicenter Radiomics in Theranostic SPECT/CT Imaging
Mohamed Saber Azimi

10:00 **MIC-05-322**
Evaluation of Dose Rate Dependent Alanine/ESR Response under Carbon Ion FLASH Irradiation
Chul Hee Min

11:30 **MIC-05-325**
Preclinical Evaluation of an In-Room All-Digital PET System for Post-Irradiation Proton Range Verification
Qingguo Xie

13:00 **MIC-05-328**
Proton range verification via coaxial prompt gamma-ray monitoring: experimental proof-of-concept at clinical beam currents
Fernando Hueso-González

14:30 **MIC-05-331**
Sub-Millimeter Range Verification in Carbon-Ion Therapy Using In-Beam All-Digital PET
Qingguo Xie

16:00 **MIC-05-334**
Effect of Radionuclide Distribution on DNA Damage Yields: A Comparative Study between ^{134}Ce/^{134}La and other radionuclides
Sangho Lee

17:30 **MIC-05-337**
Range Monitoring and Tissue Identification in Particle Therapy with the TIARA Detector
Sara Marcatili

19:00 **MIC-05-340**
Secondary Electron Bremsstrahlung Imaging with a Knife-Edge Slit Camera for Range Verification in Carbon-Ion Therapy
Michiko Tsuda

20:30 **MIC-05-343**
A Deep Learning-Based 3D Dose Reconstruction Using a Dual-Panel PET in Proton Therapy
Xiaolong Jiang

22:00 **MIC-05-346**
Validation of Dose-to-PET Conversion for OpenPET Range Verification in Carbon-Ion Therapy
Hideaki Tashima

23:30 **MIC-05-349**
EasyPET.3D imaging of positron-emitter distributions in proton-irradiated PMMA phantoms
Ana Luísa M. Silva

1:00 **MIC-05-352**
Dosimetry-Oriented Structure-Weighted CT-Guided Registration for Multi-Time-Point SPECT/CT in Radionuclide Therapy
Yanzhen Du

2:30 **MIC-05-355**
Characterization and biological validation of a BNCT irradiation field using PADC detectors, RCF and microdosimetric modelling
Joan Flors Marti

4:00 **MIC-05-358**
MACACO III+ Compton camera imaging of ^{225}Ac in mice
Karol Brzeziński

5:30 **MIC-05-361**
Boron Imaging with a Compton Camera: Toward Real-Time Dosimetry in BNCT Treatments
Pablo Torres-Sánchez

7:00 **MIC-05-364**
Feasibility of In-vivo Dosimetry for Proton Therapy using a Mobile Point-of-Care (PoC) PET Imaging System
Samarth Aggarwal

8:30 **MIC-05-367**
Unfolding Temporal Behavior in Emerging ^{161}Tb-FAPI-2286 Dosimetry: Role of Partial Volume Correction in Lesion and Organ Quantification
Mohamed Saber Azimi

10:00 **MIC-05-370**
COXIRIS: A Novel Real-Time Platform for Integrated Cancer Detection, Medical Imagen and Targeted Treatment; Deep EDXRF Detection

Bryan Casanelli, National Research and Development Agency of Chile (ANID) and the Frontera Uninversity

11:30 **MIC-05-373**
Attenuation Correction Using 176Lu Background in Limited-Angle Flat-Panel Total-Body PET
Thibault D'Hulster

13:00 **MIC-05-376**
System Characterization of a DOI-Enabled High-Resolution Total-Body TOF PET Scanner
Qiyu Peng

14:30 **MIC-05-379**
Implementation and Evaluation of TOF and Scatter correction for the IMAS TB-PET
Antonio J. Gonzalez

16:00 **MIC-05-382**
Addressing Scatter Phantom Length Limitations: A Single-Scan Multi-Position Method for NEMA NU 2 Testing of Long Axial FOV PET Systems
Liuchun He

17:30 **MIC-05-385**
Characterizing Smoking Effects Across Lung Cancer Subtypes by Integrating Systemic Metabolic Networks and Tumor Habitat Imaging from Total-Body ^{18}F-FDG PET/CT
Haiyan Wang

19:00 **MIC-05-388**
Improving Generalization of PET Image-Enhancing Deep Learned Models Through Domain Randomization
Pablo Aguiar

20:30 **MIC-05-391**
Unsupervised Deep Learning for Prompt Gamma Emission Reconstruction in Time and Space
Julius Werner

22:00 **MIC-05-394**
Supervised Contrastive Pretraining Enables Few-Shot Alzheimer's Disease Classification on Multi-Site ECD SPECT
Yu-Ching Ni

23:30 **MIC-05-397**
Large Language Models for Generating Descriptions of 3D Medical Image Volumes
Joshua Schaefferkoetter

1:00 **MIC-05-400**
Preliminary Region-Aware MRI-to-sCT Synthesis for Radiotherapy-Oriented Imaging in Nasopharyngeal Carcinoma
Zhigang Sun

2:30 **MIC-05-403**
Deep Learning-Based Tau Positivity Estimation from Multimodal Amyloid and FDG PET
Yiyi Hu

4:00 **MIC-05-406**
Compton Camera Image Reconstruction Using Compton Physics-Prior Fusion and Set Transformers for Actinium-225 Targeted Alpha Therapy
Yazeed Balasmeh

5:30 **MIC-05-409**
CNN-Based Classification Performance Across Axial, Coronal, and Sagittal Imaging Orientations in ^{18}F-PSMA PET Images
Anting Li

7:00 **MIC-05-412**

8:30 **MIC-05-415**
Equilibrium Matching for PET Image Denoising: Signal vs. Velocity Parameterization Under Identical Conditions
Shaghayegh Afshari

10:00 **MIC-05-418**
CT-VDETR: Semi-supervised 3D Trauma Detection in Computed Tomography (CT) scans using Dense Vertex Relative Position Encoding
Shivam Chaudhary

11:30 **MIC-05-421**
An AI Model for Breast Density Estimation using Spectroscopic X-Ray Data
Megan A. Eaton

13:00 **MIC-05-424**
Positron Range Correction with Texture Preservation in ^{82}Rb PET
Nerea Encina-Baranda

14:30 **MIC-05-430**
Genetic algorithm-based PET sinogram denoising using a Poisson noise fitness criterion
Fernando Guedan

16:00 **MIC-05-433**
Comparative Analysis of Cross-Validation Strategies for Classification of Major Adverse Cardiac Events Using Stress-phase PET Polar Maps
Monire Vatandoust, Monire Vatandoust

17:30 **MIC-05-436**
High-Sensitivity Compton Imaging via a Virtual Multi-Stage Edge-On CZT Architecture
Greyson Shoop

19:00 **MIC-05-439**
3D reconstruction of radioluminescence microscopy data via MAP with optimized total variation regularization
Youngho Seo

20:30 **MIC-05-442**
Physics-Informed Jointly Constrained Spectral Signal Decomposition for High-Resolution X-Ray Fluorescence Computed Tomography
Liang Li

22:00 **MIC-05-445**
Evaluation of Dual Tracer [^{18}F]FDG:[^{11}C]choline PET: A Simulation Study
Avishan Elkayee Dehno

23:30 **MIC-05-448**
EduPET - Development of a portable benchtop ToF-PET system for educational applications
Ana Luísa M. Silva, On behalf of EduPET Collaboration

1:00 **MIC-05-451**
Telephoto-Lens Magic-Cube: A Hybrid-Encoded Portable Gamma Camera for Extended-Distance Intraoperative Radiotracer Imaging
Yuxi Zhang

2:30 **MIC-05-454**
Whole gamma imaging prototype V: a proof-of-concept system with thin HRGAGG toward simultaneous PET/SPECT imaging
Go Akamatsu

4:00 **MIC-05-457**
Methodology to determine the absolute values of 3γ/2γ annihilation rate ratio with J-PET
Neha Chug, On behalf of J-PET collaboration

5:30 **MIC-05-460**
Development of MACACOX2 dual-Compton camera system
Siddharth Parashari

7:00 **MIC-05-463**
MEDICAL THERMAL TOMOGRAPHY: EXPERIMENTAL DEMONSTRATION WITH HARDWARE PHANTOMS
Anna Frixou

8:30 **MIC-05-466**

10:00 **MIC-05-469**
A Computational Assessment of Quantum SimulationVersus Classical Simulation for Quantum-InspiredMedical Imaging
Hamid Sabet

12 November, 2026

9:00 – 11:00 FEDERICO GARCÍA LORCA
MP-02 MIC Plenary Session 2

Chairs:
Vesna Sossi (Vancouver)
Roger Fulton (Sydney)

9:00 **MP-02-01**
NPSS President
Sara A. Pozzi, Vesna Sossi, Roger Fulton

9:10 **MP-02-02**
Plenary Talk | Nuclear Fusion – Energy source for the future: An overview with emphasis on control and imaging
Axel Winter

10:00 **MP-02-03**
NPSS merit award Introduction
Steven R. Meikle

10:05 **MP-02-04**
NPSS merit award presentation
Tba Tba

10:15 **MP-02-05**
Edward J. Hoffman Medical Imaging Scientist Award Introduction
Youngho Seo

10:17 **MP-02-06**
Edward J. Hoffman Medical Imaging Scientist Awardee Introduction
Suleman Surti

10:19 **MP-02-07**
Edward J. Hoffman Medical Imaging Scientist Awardee Presentation
Dimitris Visvikis

10:29 **MP-02-08**
Freek J. Beekman Medical Imaging Technical Achievement Award Introduction
Youngho Seo

10:31 **MP-02-09**
Freek J. Beekman Medical Imaging Technical Achievement Awardee Introduction
Xiaochuan Pan

10:33 **MP-02-10**
Freek J. Beekman Medical Imaging Technical Achievement Awardee Presentation
Ken Taguchi

10:43 **MP-02-11**
Bruce H. Hasegawa Young Investigator Medical Imaging Award Introduction
Youngho Seo

10:45 **MP-02-12**
Bruce H. Hasegawa Young Investigator Medical Imaging Awardee Introduction
Ciprian Catana

10:47 **MP-02-13**
Bruce H. Hasegawa Young Investigator Medical Imaging Awardee Presentation
Kevin Jaeyoung Chung

10:52 **MP-02-14**
IEEE TRPMS Best Paper Award
Dimitris Visvikis

11:30 – 12:45 FEDERICO GARCÍA LORCA
MIC-06 Simulation and modeling of medical imaging systems (1)

Chairs:
Julien Bert (Brest)
Min Sun Lee (Daegu)

11:30 **MIC-06-01**
Minkhole Collimators for SPECT: Minkowski-Sum Aperture Geometry and Closed-Form Ray Tracing
Yusheng Li

11:45 **MIC-06-02**
Monte Carlo simulation model of the ring CZT based VERITON SPECT-CT system
David Sarrut

12:00 **MIC-06-03**
Intraoperative Position-Sensitive Positron Emission Counter (PEC): A Simulation Study
Ryotaro Ohashi

12:15 **MIC-06-04**
A metascintillator-based, ultra-ToF enabled, brain PET scanner simulation
Georgios Konstantinou

12:30 **MIC-06-05**
Towards the Ultimate Sub-0.4 mm Resolution: GATE Simulation of a Mouse Brain PET System
Han Gyu Kang

11:30 – 12:45 MANUEL DE FALLA
MIC-07 Multi-modality imaging systems including applications and High resolution imaging systems (organ-dedicated, small animal systems) (2)

Chairs:
Volkmar Schulz (Aachen)
Nikos Efthimiou (Groningen)

11:30 **MIC-07-01**
Experimental Feasibility of Dual-Mode C-arm CT/SPECT Imaging Using a Commercial X-ray Detector for Online Brachytherapy Delivery Verification
Saerom Sung

11:45 **MIC-07-02**
Development of Biological Microenvironment Imaging Technique Using ^{111}In Cascade

Gamma-Ray Correlation
Boyu Feng

12:00 **MIC-07-03**
SmartBrain-EEG: First-in-Human Wearable PET/EEG Imaging in Epilepsy
Han Liu, Han Liu

12:15 **MIC-07-04**
Human Subject and Phantom Imaging Performance of PETcoil Gen II Brain-Dedicated PET System
Grant H.-S. Park

12:30 **MIC-07-05**
Development of SIAT 9.4T MRI compatible animal PET scanner
Haonan Li

12:45 – 13:05 FEDERICO GARCÍA LORCA
M-LT-03 New radiation detector technologies for medical imaging,Novel applications of AI in radiation-based medical imaging

Chairs:
Min Sun Lee (Daegu)
Julien Bert (Brest)

12:45 **M-LT-03-01**
MRI-Informed SPECT-only Spatial Normalization for Reliable Brain Perfusion Quantification
Euijin You

12:47 **M-LT-03-02**
Developments in fabrication and design flexibility of amorphous silicon microchannel plates
Georgios Konstantinou

12:49 **M-LT-03-03**
Fabrication of diamond detectors with graphitic contacts for tissue equivalent dosimetry
Ivan Lopez Paz, Ivan Lopez Paz

12:51 **M-LT-03-04**
Scintillation Properties of $(Lu,Y)_2O_3$:La Ceramic Pixels for PET
Jarek Glodo

12:53 **M-LT-03-05**
Ultrahigh Spatial Resolution Perovskite-based Direct X-ray Imagers for Low-lag Medical

Applications
Amlan Datta

12:55 **M-LT-03-06**
PhysiCal-PET: Physics-based neural networks for the rapid position Calibration of PET Scanners
Mojahed Abushawish

12:57 **M-LT-03-07**
Adaptive Spatio-Temporal Denoising for Low-Dose Fluoroscopy via Motion-Gradient Weighting
Nerea León

12:59 **M-LT-03-08**
An Ensemble of Deep-Learning Classifiers for 3D Anatomical Change Reconstruction in Carbon-Ion Radiotherapy (CIRT)
Maria Martisikova

13:01 **M-LT-03-09**
Zero-Shot PET Image Super-Resolution via Cross-Modal Mutual Information Guidance
Yilin He

13:03 **M-LT-03-10**
3D Photon Position Estimation Using Neural Networks in Monolithic-Based PET Systems
Marta Freire

12:45 – 13:05 MANUEL DE FALLA

M-LT-04 New radiation detector technologies for medical imaging, Simulation and modeling of medical imaging system, Multi-modality imaging systems including applicationss

Chairs:
Volkmar Schulz (Aachen)
Nikos Efthimiou (Groningen)

12:45 **M-LT-04-01**
Development of a PET/MRI Compatible Fluorescence Microscope for Simultaneous Cell Tracking in a Small Animal PET/MRI Scanner
Philipp Renn

12:47 **M-LT-04-02**
Hybrid PGI-PET Imaging for Ion-Range Monitoring in Hadron Therapy
Javier Balibrea-Correa

12:49 **M-LT-04-03**
Intercrystal Compton Scattering Detection in Pixelated LYSO Detectors via Quantum Localization
Amirreza Hashemi

12:51 **M-LT-04-04**
PETRARCA: a Positron Emission Tomography Real-Time Analog Re-Configurable ANN Detector
Maurizio Pandocchi

12:53 **M-LT-04-05**
MIMOSA: Medical IMaging MOnte Carlo Simulation Algorithms for fast proton therapy range monitoring
Declan D. Garvey

12:55 **M-LT-04-06**
Analytical modeling and inclusion of object scatter in non-TOF 3D PET for low-count data
Jorge Roser

12:57 **M-LT-04-07**
Quantitative Impact of Inter-Crystal Scatter on Image Quality and Sensitivity across LabPET-II Scanner Architectures: A Comparative GATE Simulation Study
Alexandre Bernier

12:59 **M-LT-04-08**
Validated Optical Simulation for High-Energy Gamma Response in a 3-Layer LYSO DOI Detector
Shan Jiang

13:01 **M-LT-04-09**
Identification of ICS Pixels in a high-resolution 3-Layer DOI-PET Detector Using a CNN
Shan Jiang

13:03 **M-LT-04-10**
Study on the axial extension of the small-fish PET scanner MERMAID
Magdalena Kolodziej

15:00 – 17:00 FEDERICO GARCÍA LORCA
MIC-08 Novel applications of AI in radiation-based medical imaging (1)

Chairs:
Quanzheng Li (Boston)
Nicolas A. Karakatsanis (New York)

15:00 **MIC-08-01**
Sensitivity-Informed Network for Image Restoration in Sparse-Detector PET
Yucun Hou

15:15 **MIC-08-02**
Anatomy-Guided Null-Space Learning for Self-Supervised Blind PET Deblurring
Ziyuan Zhou

15:30 **MIC-08-03**
Brownian Bridge Diffusion Model for Ultra-Low-Dose Total-Body PET Denoising
Narges Aghakhanolia

15:45 **MIC-08-04**
Self-Supervised Low-Dose SPECT Denoising from a Single Standard-Dose Scan via Poisson Thinning
Haowen Zheng

16:00 **MIC-08-05**
VLM-Guided Conditional Flow Matching for CT-Free total-body PET Correction
Jianming Rong

16:15 **MIC-08-06**
Implicit Neural Representations for Joint Motion-Resolved PET Reconstruction and Respiratory Gating
Nicolas De Bie

16:30 **MIC-08-07**
Towards CT-Free Multi-Time-Point [^{18}F]PSMA-1007 LAFOV PET Protocols: Evaluation of Synthetic Attenuation Maps Versus Elastic Co-Registration for Longitudinal Imaging
Elnaz Olyaei, Elnaz Olyaei

16:45 **MIC-08-08**
3D Latent Implicit Diffusion for Scalable Volume Generation
Antoine De Paepe

15:00 – 17:00 MANUEL DE FALLA
MIC-09 New radiation detector technologies for medical imaging (1)

Chairs:
Joshua W. Cates (Berkeley)
Marta Freire (Valencia)

15:00 **MIC-09-01**
Deep learning-based estimation of individual scintillation photon arrival times for

enhanced TOF resolution
Yuya Onishi, Yuya Onishi

15:15 **MIC-09-02**
Inter-Crystal Scattering Recovery in Semi-Monolithic Crystals: an Experimental and Simulation Study
Fiammetta Pagano

15:30 **MIC-09-03**
A High Resolution Semi-Monolithic GAGG Detector Aiming for SPECT Imaging
Yangyang Zhao

15:45 **MIC-09-04**
Feasibility of Cherenkov-only Radiation Emitters Coupled to SiPMs for PET
Afonso Xavier Pinto

16:00 **MIC-09-05**
Scan Time and Effective Dose Reduction using an Ultra-Fast Molecular Breast Imaging System
Alexander Cherlin

16:15 **MIC-09-06**
Scalable Cherenkov-Enhanced Timing in BGO with FastIC+
Francis Loignon-Houle

16:30 **MIC-09-07**
An Optimized Two-Layer PET&SPECT Shared Detector based on a Scintillator-as-Collimator Design
Yangyang Zhao

16:45 **MIC-09-08**
Unlocking Next-Generation Time-of-Flight Imaging with the PoETIC ASIC
David Gascón

17:30 – 19:00 Poster Area
MIC-10 MIC Poster Session 2

Chairs:
Dennis R. Schaart (Delft)
Hideaki Tashima (Chiba)

17:30 **MIC-10-002**
Detection efficiency of a lead-loaded plastic scintillator for positron emission

tomography detectors : A Monte Carlo study
Makoto Yamazaki

17:30 **MIC-10-005**
Exploring CTR improvement through structural refinement of orthogonally stacked PET detector
Ryosuke Ota

17:30 **MIC-10-008**
A Cost-Effective Neural Network Approach for DOI Estimation in a State-of-the-Art PET Detector
Qi Liu

17:30 **MIC-10-011**
X-ray Imaging Performance of Mg Co-doped $Y_3(Al,Ga)_5O_{12}$:Ce for Photon-counting CT
Hisato Suezumi

17:30 **MIC-10-014**
Optimal Radiator Refractive Index for Cherenkov-Radiator-Integrated PET Detectors: A Simulation Study
Taiyo Ishikawa

17:30 **MIC-10-017**
Fabrication of diamond detectors with graphitic contacts for tissue equivalent dosimetry
Ivan Lopez Paz, Ivan Lopez Paz

17:30 **MIC-10-020**
Experimental Evaluation of Classification MLP for Position Estimation in Semi-Monolithic LYSO Cassettes for Ultra-High-Performance Brain PET
Nicolas A. Karakatsanis

17:30 **MIC-10-023**
AI-based DOI determination for hexagonal monolithic LYSO scintillators with hexagonal cells engraved with laser: A simulation/experiment study
Jose Udias

17:30 **MIC-10-026**
Exploring the Performance of Light-Sharing Based Single-ended BGO DOI-PET Detectors
Yong Hwan Sul

17:30 **MIC-10-029**
Experimental Evaluation of Coincidence Time Resolution in LYSO Scintillators with

Photonic Crystal Pattern
Suyeon Hyeon

17:30 **MIC-10-032**
X-ray fluorescence imaging for breast cancer characterization within the IMMPRINT project
Karol Brzeziński

17:30 **MIC-10-035**
Characterization of DOI-enabled Three-Layer Trapezoidal Pixelated LYSO Detector
Siddharth Parashari

17:30 **MIC-10-038**
PETRARCA: a Positron Emission Tomography Real-Time Analog Re-Configurable ANN Detector
Maurizio Pandocchi

17:30 **MIC-10-041**
Scintillation Properties of $(Lu,Y)_2O_3$:La Ceramic Pixels for PET
Jarek Glodo

17:30 **MIC-10-044**
Ultrahigh Spatial Resolution Perovskite-based Direct X-ray Imagers for Low-lag Medical Applications
Amlan Datta

17:30 **MIC-10-047**
Timing and Spatial Properties of HRPPD coupled to LGSO/LYSO for TOF-PET Applications
Chien-Min Kao

17:30 **MIC-10-050**
Analytical modeling and inclusion of object scatter in non-TOF 3D PET for low-count data
Jorge Roser

17:30 **MIC-10-053**
Noise Modeling of Three Material Dual Energy Computed Tomography with a Pathlength Constraint
Andrew E. Ferretti

17:30 **MIC-10-056**
Optimization of Pinhole Diameter in Fully Stationary Multi-Pinhole Brain SPECT:

Prioritizing Spatial Resolution via CNN-Based Correction
Takumi Akatsuka

17:30 **MIC-10-059**
Validated Optical Simulation for High-Energy Gamma Response in a 3-Layer LYSO DOI Detector
Shan Jiang

17:30 **MIC-10-062**
A Mesh-Type Reference Computational Phantom Platform for Multi-Modality Monte Carlo Simulation in OpenGATE
Jin Jegal

17:30 **MIC-10-065**
Inter-Crystal Scattering in LYSO-SiPM PET: Integrated Analysis via Geant4/GATE Simulation, CNN, and Multi-Pitch Experiments
Tianyi Deng

17:30 **MIC-10-068**
Design of a brain SPECT scanner based on high intrinsic resolution CZT detectors and multi-pinhole collimators
Kris Thielemans

17:30 **MIC-10-071**
Modeling analog SiPMs with temporal crosstalk integration for fast timing in medical imaging
Nicolaus Kratochwil

17:30 **MIC-10-074**
Study on the axial extension of the small-fish PET scanner MERMAID
Magdalena Kolodziej

17:30 **MIC-10-077**
Design and Modeling of BetaBox 2.0: a System for Quantitative Measurement of Beta Emitters in Single Cells
Kyle Klein

17:30 **MIC-10-080**
Hardware Ray-Tracing-Accelerated Optical Photon Transport in TOPAS on Apple Silicon
YoungMoon Goh

17:30 **MIC-10-083**
Identification of ICS Pixels in a high-resolution 3-Layer DOI-PET Detector Using a CNN
Shan Jiang

17:30 **MIC-10-086**
Impact of PET energy window extent on trues normalization and reconstructions
Simon Noë

17:30 **MIC-10-089**
MIMOSA: Medical IMaging MOnte Carlo Simulation Algorithms for fast proton therapy range monitoring
Declan D. Garvey

17:30 **MIC-10-092**
Quantitative Impact of Inter-Crystal Scatter on Image Quality and Sensitivity across LabPET-II Scanner Architectures: A Comparative GATE Simulation Study
Alexandre Bernier

17:30 **MIC-10-095**
Effects of Beam Filtration on Time-of-Flight-Based Scatter Rejection in Computed Tomography
Guen Bae Ko

17:30 **MIC-10-098**
Hybrid PGI-PET Imaging for Ion-Range Monitoring in Hadron Therapy
Javier Balibrea-Correa

17:30 **MIC-10-101**
Development of a PET/MRI Compatible Fluorescence Microscope for Simultaneous Cell Tracking in a Small Animal PET/MRI Scanner
Philipp Renn

17:30 **MIC-10-104**
Toward Simultaneous PET/SPECT/MR System for Theranostic Imaging
Yifei Jin

17:30 **MIC-10-107**
Development of a Preclinical Simultaneous Ultrasensitive SPECT and PET Imager
Ruiying Zhu

17:30 **MIC-10-110**
A Dual-Ring Super-Resolution PET System
Chien-Min Kao

17:30 **MIC-10-113**
Performance Evaluation of a DOI-Enabled Dedicated Brain PETCT System
Qiyu Peng

17:30 **MIC-10-116**
Design and Preliminary Validation of a Heart-Dedicated TOF-PET Scanner with Sub-250ps Timing Resolution
Qiyu Peng

17:30 **MIC-10-119**
Design and Quantitative Characterization of a High-Performance Brain-Dedicated PET System via Virtual Pinhole PET Technique
Yihao Chen

17:30 **MIC-10-122**
Design and Performance Characterization of a Sparsely Populated DOI capable Breast PET/MRI Insert
Janina Hohnholz

17:30 **MIC-10-125**
Enabling DOI capability in Low-Cost BGO PET System for Small-Animal Imaging
Haoyu Zou

17:30 **MIC-10-128**
Nested plastic scintillator PET detector geometries have distinct spatial resolution advantages
Martin Rädler, On behalf of the J-PET collaboration

17:30 **MIC-10-131**
Adapt-PET: A Hardware-Algorithm Co-evolution Framework for Versatile, Ultra-High-Resolution Targeted Imaging
Jianyong Jiang

17:30 **MIC-10-134**

17:30 **MIC-10-137**
Performance evaluation of the third generation of TOF-DOI Prism-PET detector modules
Soroush Shabani Sichani

17:30 **MIC-10-140**
Clinical Validation of MoDeCo: A Motion Detection and Correction Method for a

Dedicated Brain PET Scanner
Enrique Muñoz

17:30 **MIC-10-143**
Impact of beam hardening and detector response function corrections when using photon-counting imaging detectors
Hiroaki Hayashi

17:30 **MIC-10-146**
Evaluation of Lead-Free Composite for X-ray Shielding using LD-V1 Film
Seungwoo Park

17:30 **MIC-10-149**
Evaluation of image resolution for Novel Dual-energy X-ray Absorptiometry System
Hyuntae Leem

17:30 **MIC-10-152**
Physics-Guided Retinexformer for Beam Hardening Artifact Correction in Rock CBCT
Yuanjue Ma

17:30 **MIC-10-155**

17:30 **MIC-10-158**
Mitigating Scatter-Induced BMD Errors in Wide Fan-Beam DXA Using Anti-Scatter Grids
Myungwoo Oh

17:30 **MIC-10-161**
Empirical Decomposition for Quantification of Multi-Contrast-Agent
Zhe Wang

17:30 **MIC-10-164**
Empirical Correction of Detector Response for Quantitative X-Ray Transmission Modelling and its Application to Computed Tomography
Qingxiang Chen

17:30 **MIC-10-167**
Synthetic generation of the dental anatomy for cone-beam CT simulation from patient data
Idris Tatachak

17:30 **MIC-10-170**
Image Quality Evaluation of Cone Beam Computed Tomography (CBCT) in an O-arm

Fluoroscopy Machine Using the SedentexCT IQ Phantom
John Patrick Ryan S. De Guzman

17:30 **MIC-10-173**
Validation of conventional mammography material decomposition using VICTRE simulated breast data
Xiaochuan Pan

17:30 **MIC-10-176**

17:30 **MIC-10-179**
Development of a 64-Channel Energy and Timing Acquisition System for TOF-DXA
Sang-Hyun Chun

17:30 **MIC-10-182**
GARM: Geometry-Aware Reconstruction Method for Static CT Generalizable across Diverse Scanning Strategies
Peixuan Song

17:30 **MIC-10-185**
Impact of Small-Angle Event Selection in Compton Cone Imaging
Elisabetta Medina

17:30 **MIC-10-188**
Deep Learning-based 3D SPECT Reconstruction from Biplanar Projections and CT Scout Views
Jiarui Huang

17:30 **MIC-10-191**
The Inverse Problem of Spatiotemporal Emission Reconstruction from Prompt Gamma Timing Data
Julius Werner

17:30 **MIC-10-194**
Recent updates to STIR, a community effort of a quarter century
Nikos Efthimiou

17:30 **MIC-10-197**
Developments in fabrication and design flexibility of amorphous silicon microchannel plates
Georgios Konstantinou

17:30 **MIC-10-200**
A Universal Geometric Calibration Method for CBCT Systems with Arbitrary Trajectories
Tong Jia

17:30 **MIC-10-203**
CT-less Attenuation Maps as Priors for Robust Joint Activity–Attenuation Estimation in TOF and Non-TOF PET
Elise Emond

17:30 **MIC-10-206**
Convergence-Informed AI-Assisted Reconstruction for Dual-Panel PET Imaging
Abdollah Saberi Manesh

17:30 **MIC-10-209**
Anatomically Guided Adaptive Gaussian Representation for PET Image Reconstruction
Zhihao Li

17:30 **MIC-10-212**
MRI guided PET reconstruction in meningioma [^{68}Ga]DOTATOC patients, pituitary adenoma [^{18}F]FET, and neurodegenerative [^{18}F]FDG patients
Thomas L. Andersen

17:30 **MIC-10-215**
A Hybrid Neural Network Model for DaTscan Diagnosis of Neurodegenerative Disorders
Efstratios Roupas

17:30 **MIC-10-218**
A Global-Local Latent Diffusion Model for Limited-Angle CT Reconstruction
Tong Jia

17:30 **MIC-10-221**
Iterative proton CT reconstruction from list-mode data of a sandwich time-of-flight scanner
Aurélien Coussat

17:30 **MIC-10-224**
Direct normalization correction for a brain PET system with multi-resolution detector design
Chengzhi Yang

Gregory R. Romanchek

17:30 **MIC-10-464**
Enhancement of Charged-Particle Shielding via Lightweight Nanocomposites
Gabrielle J. Grey

17:30 **MIC-10-467**
Detector Geometry Optimization of a Sensing Collimation Imager (SCI)
Ling Cai

17:30 **MIC-10-470**
Toward Whole-Body Whole Gamma Imaging: Monte Carlo Simulation of ^{89}Zr PET-

Compton Hybrid Imaging
Mizuki Miyahara

13 November, 2026

9:00 – 11:00 FEDERICO GARCÍA LORCA
MIC-11 Young Investigator Session (oral)

Chairs:
Emilie Roncali (Davis)
Ciprian Catana (Charlestown)

9:00 **MIC-11-01**
Toward Clinical Deployment of Complex PET Designs via Fast In-System Calibration
Julian Thull, Julian Thull

9:15 **MIC-11-02**
A Compact Preclinical PET Scanner Achieving NEMA-Standard Sub-0.5 mm Spatial Resolution via Analytic FBP Reconstruction
Chenxi Li

9:30 **MIC-11-03**
Development of a ring-type Quantum Entanglement PET Imaging System and Application of a Novel Image Reconstruction Algorithm to In-Vivo Imaging
Koki Nakamura

9:45 **MIC-11-04**
SIMPLE-DIP: Positronium Lifetime Image Reconstruction Using Deep Image Prior
Bangyan Huang

10:00 **MIC-11-05**
AI-Based Predictive Dosimetry from PET for 177Lu-PSMA Radiopharmaceutical Therapy for Prostate Cancer
Bowen Lei

10:15 **MIC-11-06**
Event-Resolved Parent-Progeny Discrimination Using CMOS Lensless Radiomicroscopy for ^{225}Ac Targeted Alpha Therapy
Hyeyeun Chu

10:30 **MIC-11-07**
Physics-Guided Implicit Neural Representation for 3D Ac-225 Compton Imaging
Gyohyeok Song

10:45 **MIC-11-08**
Attenuation Map Estimation from NAC Brain PET Images Using a 3D Patch-Based U-Net: A Multi-Tracer Study on the NeuroEXPLORER
Max Keppens

9:00 – 11:00 MANUEL DE FALLA
MIC-12 New Concepts and Emerging Applications

Chairs:
Magdalena Rafecas (Lübeck)

9:00 **MIC-12-01**
Direct clinical imaging of alpha therapy in a PET/CT scanner via cascade gamma-rays imaging
Javier Caravaca

9:15 **MIC-12-02**
From MeV Gamma to PET Signal: Experimental Demonstration of Pair Production Tomography for Theranostic Imaging
Biswajit Das

9:30 **MIC-12-03**
Quantitative evaluation of pair-produced positrons using a clinical linear accelerator for pair-production tomography
Ryosuke Ota

9:45 **MIC-12-04**
Terbium-149: a Laboratory for Three-Photon Events
Lorenzo Mercolli

10:00 **MIC-12-05**
The first in vivo quantum entanglement imaging of a human subject
Pawel Moskal

10:15 **MIC-12-06**
Constraining CP Invariance in Ortho-Positronium Decays at 7 T with NeuroSphere MR-Compatible PET Modules
Magdelena S. Allen

10:30 **MIC-12-07**
Novel Spatial Encoding Using Larmor Precession in Nuclear Medicine: A Study on Imaging Robustness
Hiroto Suzuki

10:45 **MIC-12-08**
Real-Time Task-Based Adaptive SPECT Imaging via Optimized System Sampling Strategies Using a Robotic Clinical SPECT Platform
Yifei Jin

11:30 – 12:45 FEDERICO GARCÍA LORCA
MIC-13 New radiation detector technologies for medical imaging (2)

Chairs:
Paul R. Lecoq (Geneva)
Han Gyu Kang (Chiba)

11:30 **MIC-13-01**
Cramér–Rao–Efficient Timing with Photon Counting: Theory and Proof-of-Concept Demonstration for Cherenkov TOF-PET
Nicolaus Kratochwil

11:45 **MIC-13-02**
Sparse-to-Dense SiPM Readout Upsampling for Position Estimation in PET Detectors
Francis Loignon-Houle

12:00 **MIC-13-03**
Crosshair Light-Sharing Detectors with Diode-based Multiplexing for High-Resolution TOF-DOI PET
Han Gyu Kang

12:15 **MIC-13-04**
High-performance 4×4-channel microchannel plate photomultiplier tubes with bismuth germanate window faceplate
Ryosuke Ota

12:30 **MIC-13-05**
Achieving Sub-100 ps CTR and Sub-2 mm DOI Resolution in TOF-PET Modules
Giulia Terragni

11:30 – 12:45 MANUEL DE FALLA
MIC-14 Novel applications of AI in radiation-based medical imaging (2)

Chairs:
Joyita Dutta (Amherst)

11:30 **MIC-14-01**
Deep Learning Limited Angle Artefact Correction for dual panel PET in Shearlet Domain
Jens Maebe

11:45 **MIC-14-02**
Multi-Objective Bayesian Optimization of Self-Collimating SPECT System Design Using Quantitative Imaging Metrics
Syed O. Shah

12:00 **MIC-14-03**
Sensitivity-Aware Gated Deep Reconstruction for Cascade γ Coincidence Imaging
Hao Jia

12:15 **MIC-14-04**
Two-Stage Retrieval-Augmented 3D Detection of Bone Metastatic Lesions via SPECT/CT
Yangshi Lin

12:30 **MIC-14-05**
Data Augmentation Strategy Analysis for Noninvasive Lung Cancer Subtype Classification
Xinyu Hu

12:45 – 13:05 FEDERICO GARCÍA LORCA
M-LT-05 Kinetic modeling, molecular connectivity analysis and radiomics, Theranostics, Imaging and dosimetry in therapy (particle, radiopharmaceutical, surgery), Total body imaging systems including applications

Chairs:
Paul R. Lecoq (Geneva)
Han Gyu Kang (Chiba)

12:45 **M-LT-05-01**
Pixelated Cherenkov Crystals for Prompt-Gamma Imaging in Proton Range Verification
Leonor Rebolo

12:47 **M-LT-05-02**
Coded-Mask PGI for Proton Range Verification With Pure Cherenkov Crystal Detectors
Salvador M. Gómez

12:49 **M-LT-05-03**
Deep Learning-based CT-Free Deformable Registration for PET-CT Misalignment Correction
Abolfazl Mehranian

12:51 **M-LT-05-04**
Evaluation of TOF-DOI Crystal Topologies for the HD-MetaPET MRI Insert
Thore Meyer

12:53 **M-LT-05-05**
Noise-Robust Bayesian Parameter Estimation of Two-Tissue Compartment Kinetic Model for dynamic SPECT imaging
Dandan Zhang

12:55 **M-LT-05-06**
Conditional Flow-Matching-based Kinetic Refinement for Low-Count SRTM-based Parametric Imaging in Dynamic PET
Yu Jin Seol, Yu Jin Seol

12:57 **M-LT-05-07**
Attenuation Images from Time-of-Flight PET for Metal Artifact Reduction: A Phantom Study
Ann-Kristin Lüvelsmeyer

12:59 **M-LT-05-08**
An FPGA-based data acquisition system for remote wireless radiation monitoring
Robert S. Miyaoka

13:01 **M-LT-05-09**
Energy-Shifting: an efficient approach for Monte Carlo Particle Therapy Dose Calculation
Julien Bert

13:03 **M-LT-05-10**
Treatment Monitoring System for Proton Therapy Based on Beam Range Measurement
SeHyun Jang

12:45 – 13:05 MANUEL DE FALLA
M-LT-06 Signal and Data Processing, New Concepts and Emerging Applications

Chairs:
Joyita Dutta (Amherst)

12:45 **M-LT-06-01**
Development of a Dual-Modality Imaging Capsule for Laparoscopic Radio-Guided Surgery
Krishan Patel

12:47 **M-LT-06-02**
Development of a High Sensitivity Cascade Gamma Photon Coincidence Imaging System
Qingyang Wei

12:49 **M-LT-06-03**
Quantum entanglement of annihilation photons as a function of the annihilation

mechanism
Deepak Kumar

12:51 **M-LT-06-04**
First In-Vivo Positronium Ratio Imaging (PRI) using F-18 FDG: A Preliminary Study with Phantom and a Mouse Model
Macoto Fujimoto

12:53 **M-LT-06-05**
Quantitative 4D PET Imaging of Photosynthate Transport and Rhizosphere Carbon Partitioning in Intact Plant–Soil Systems
Muhammad Nasir Ullah

12:55 **M-LT-06-06**
Comparative Evaluation of Respiratory Motion Correction Methods for Upright Walk-Through PET Using XCAT Simulations
Rabia Aziz

12:57 **M-LT-06-07**
Dementia Risk Estimation From a Positron Emission Tomography-Derived Latent Biomarker
Cristóbal Vázquez García

12:59 **M-LT-06-08**
Data-Driven Selection of Representative Motion Models for Simulation in Dynamic Cardiac PET
Nader Nemati, Nader Nemati

13:01 **M-LT-06-09**
A Quality Control Framework for Deep Learning-based Attenuation Map Synthesis in PET
Yihuan Lu

13:03 **M-LT-06-10**
Characterizing Noise in Clinical Nuclear Medicine Modalities via Quantum-Inspired Framework
Amirreza Hashemi

15:00 – 17:00 Poster Area
MIC-15 MIC Poster Session 3

Chairs:
Georg Schramm
Charalampos Tsoumpas (Groningen)

15:00 **MIC-15-003**
Dual-ended Redout PET Detectors based on 0.25 mm pitch LYSO/GAGG arrays
Junwei Du

15:00 **MIC-15-006**
Study of the response of comercial CMOS sensors to soft X-rays
Lucía Velasco

15:00 **MIC-15-009**
Asymmetric dual-ended readout using diode-based multiplexing circuits for TOF-DOI PET detectors
Ruipeng Dai

15:00 **MIC-15-012**
Development of a TOF-DOI PET Detector Using Dual-ended Interleaved Multiplexing Readout
Xiaolong Jiang

15:00 **MIC-15-015**
Design of a Single-Ended Readout DOI PET Detector with BGO and Deep Learning
Sungwook Hong

15:00 **MIC-15-018**
A pulse-train model for X-ray photon-counting scintillation detectors with pile-up
Lukas Schröder

15:00 **MIC-15-021**
Monte Carlo Simulations of a Penumbra-Based Collimator-less SPECT Detector for Targeted Radionuclide Therapy Monitoring
Iara Neves

15:00 **MIC-15-024**
A covariance-based framework for quantifying circuit and intrinsic CTR limits in TOF-PET detectors
Hyeongseok Shim

15:00 **MIC-15-027**
Identification and Mitigation of Inter-Crystal Scatter in Dual-Layer DOI Configurations Under Highly Multiplexed Readout
Lukas U. Rauscher

15:00 **MIC-15-030**
Characterization of a multiplexed SiPM readout with free-running ADC for BGO PET

detectors
Nicola Belcari

15:00 **MIC-15-033**

15:00 **MIC-15-036**
Evaluating a novel type of silicon photomultiplier for X-ray photon-counting CT applications
Lukas Schröder

15:00 **MIC-15-039**
Ultra-High-Definition, 8 µm pitch, Low-Dose X-ray Detector for Microfocus Clinical Applications: From Dental to Medical Imaging
Michele Sannino

15:00 **MIC-15-042**
Dual-Ended Readout PET Detector Based on Semi-Monolithic Laser-Engraved Scintillators
Victor Sánchez-Tembleque

15:00 **MIC-15-045**
PETVision: An Ultra-High TOF Resolution PET System with 2.5D Modular Flat-Panel Detectors
Yue Zhuo

15:00 **MIC-15-048**
Comparative Evaluation of NUV-MT and NUV-DJ SiPM Timing Performance for TOF-PET Detector Application
Suhan Choi

15:00 **MIC-15-051**
Decomposing Optical Photon Transport in PET Detectors: Geometric Priors and Generative Models of Residual Stochasticity
Stephan Naunheim

15:00 **MIC-15-054**
Scaling TOF-PET Timing Calibration via Structured Detector-Wise Learning
Julian Thull

15:00 **MIC-15-057**
GPU-Accelerated Monte Carlo Simulation for SPECT Imaging
Feng Zhou

15:00 **MIC-15-060**
Monte Carlo Validation of a Positron Emission Mammography Scanner Using GATE 9.4: Sensitivity Analysis with an Aluminum Sleeve Phantom
Sara H. El-Sallabi

15:00 **MIC-15-063**
Heuristic seeding for GA-based optimization of halbach magnets for PET-compatible low-field MRI
Fumihiko Nishikido

15:00 **MIC-15-066**
Experimentally Validated GATE Model of a Commercial PET System with Sub-200 ps TOF
Michel Atieh

15:00 **MIC-15-069**
Experimental and simulation-guided light-sharing characterization of hexagonal laser-engraved PET detectors.
Clara N. Golhen Mateo

15:00 **MIC-15-072**
Microstructure-Informed Single-Grid Dark-Field X-ray Imaging for Breast Microcalcification Typing
Sunghoon Choi

15:00 **MIC-15-075**
SimTBPET: A faster framework for Total Body Monte Carlo PET simulations
Arnau Farré-Melero

15:00 **MIC-15-078**
Performance Comparison of Low-Multiplexing and High-Multiplexing Multi-Pinhole Collimators for a Large-Animal Cardiac SPECT System
Jiali Yan

15:00 **MIC-15-081**
Is 20 mm Still Optimal? Revisiting Scintillator Length in Modern TOF-PET Systems
Mizuki Furuta

15:00 **MIC-15-084**
Comparison Between GATE and SimSET Monte Carlo Simulations on GE Omni Legend PET scanner geometry
SeyedAmir ZamanPour

15:00 **MIC-15-087**
Hybrid Least-Square and k-Nearest-Neighbour Event Positioning for a Compact Gamma Camera with Monolithic NaI(Tl) Scintillator
Zhongyi Wu

15:00 **MIC-15-090**
Ultra-fast Positron Range Simulator for Patient-Specific PET Imaging
Robert J. Paneque-Yunta

15:00 **MIC-15-093**
Analytic Determination of Minkhole Collimator Sensitivity With Penetration
Yusheng Li

15:00 **MIC-15-096**

15:00 **MIC-15-099**
Performance evaluation of Compton-PET with MACACO-PET system
Siddharth Parashari

15:00 **MIC-15-102**
Dosimetry Assessment and Noise Scaling Laws in Proton Computed Tomography
Mara Bruzzi

15:00 **MIC-15-105**
Feasibility of 511 keV photon detection in the presence of scattered x-rays for simultaneous PET and CT imaging
Paul E. Kinahan

15:00 **MIC-15-108**
Integrating X-ray Dark-Field and Fluorescence Modalities for Molecular Imaging in Personalized Medicine: Initial Specifications of Setup Design and Integration Parameters
Xiaolei Yan

15:00 **MIC-15-111**
A Dual-Head Positron Imaging System
Matthias Streun

15:00 **MIC-15-114**
Development of the CT extension of the MERMAID PET prototype
Rebecca Kantorek

15:00 **MIC-15-117**
Initial performance evaluation of a dual-panel, high-resolution TOF-DOI PET prototype
Ming Niu

15:00 **MIC-15-120**
Development of a Four-Layer DOI Detector Based Preclinical PET System
Hang Yang

15:00 **MIC-15-123**
Experimental Evaluation of 3D Imaging Point Spread Function for the Ultra-High Performance Brain PET (UHB-PET) Scanner
Nicolas A. Karakatsanis

15:00 **MIC-15-126**
System integration of a Breast PET/MR Insert in a Whole-Body PET/MRI System: Data Driven Temperature Drift Correction and Synchronization
Janina Hohnholz

15:00 **MIC-15-129**
Performance Evaluation of the Motion-Adaptive Molecular and Behavioral Observation (MAMBO)-PET System
Francisco E. Enriquez-Mier-y-Teran

15:00 **MIC-15-132**
First experimental and phantom results of the DC-SPECT scanner: a cardiac-dedicated SPECT with Laser-Processed CsI:Tl Detector Modules
Xi Zhang

15:00 **MIC-15-135**
Validation of an Image Based Method of Estimating Mechanical Offsets in a Rotating Flat-Panel PET Scanner with Phantom and Clinical Data
Anirudh Shahi

15:00 **MIC-15-138**
Detector Stability and Effects on Time and Energy Resolution in Novel Clinical Brain PET Scanners
Luis Batres

15:00 **MIC-15-141**
Counting loss correction of photon counting detector: the need to consider the effective atomic number of the target object in clinical applications
Natsumi Kimoto, This is a collaborative study between JOB CORPORATION and Junshin Gakuen University.

15:00 **MIC-15-144**
An algorithm to generate effective atomic number and mass density images from photon-counting CT: application for lung disease assessment
Takashi Asahara

15:00 **MIC-15-147**
Dual-Energy CT Metal Artifact Reduction Using VMI-Guided Iterative Reconstruction Refinement
Sungmin Park

15:00 **MIC-15-150**
Magnification Effect Evaluation for Novel Dual-Energy X-Ray Absorptiometry System
Chanwoo Kwon

15:00 **MIC-15-153**
Transient radiative transport equation solution for ToF-CT ballistic X-ray photons
Maëlle Fromont

15:00 **MIC-15-156**
Characterization of a Photon-Counting CT Modality for Preclinical PET/CT
João F.C.A. Veloso

15:00 **MIC-15-159**
Characterization of a LYSO:Ce/SiPM detector array for photon-counting CT
João Filipe C.D.A. Veloso

15:00 **MIC-15-162**
Linearizing the Transformation from CT Hounsfield Units to Linear Attenuation Coefficient for PET Attenuation Map Generation using Virtual Non-Contrast Images
Heba Alrakh

15:00 **MIC-15-165**

15:00 **MIC-15-168**
Image Improvement in X-ray Fluorescence Computed Tomography Using Deep Image Prior with X-ray Transmission Images
Tsutomu Zeniya

15:00 **MIC-15-171**
Experimental Characterization and Materials-Driven Optimization of Fine-Pitch CZT Detectors for Photon-Counting CT
Aziz Ikhlef

15:00 **MIC-15-174**
Longitudinal Cone-Beam CT and MRI Integration for High-Fidelity Synthetic CT Generation
Vincent Jaouen

15:00 **MIC-15-177**
Dynamic hepatocyte-specific liver imaging using a two-dimensional SiPM-based photon counting CT: Comparison between healthy and liver tumor mouse models
Fitri Lucyana

15:00 **MIC-15-180**
Improved Material Decomposition Method in DXA Using Scatter-Induced Arrival Time Difference
Sena Kwon

15:00 **MIC-15-183**
Limited-Angle and Few-View Image Reconstruction Using Point Spread Functions
Gengsheng Zeng

15:00 **MIC-15-186**
Accelerating CGCIS Iterative Reconstruction Based on Location Priors from the DBP Algorithm
Kui Wang

15:00 **MIC-15-189**
DeepDreaming SPECT: Gradient-Based Reconstruction via Differentiable Physics Simulation
Francesc Massanes

Beyond short-lived positron emitters: feasibility of ^{18}F detection for range verification in carbon ion therapy
Akram Hamato

14 November, 2026

9:00 – 11:00 **FEDERICO GARCÍA LORCA**
MIC-18 **Advanced tomographic reconstruction techniques (2)**

Chairs:
Jinyi Qi (Davis)

9:00 **MIC-18-01**
Steerable Kernel Based Emission Tomography Reconstruction
Huanzhe Wei

9:15 **MIC-18-02**
Cross-Tracer PET Image Reconstruction Using an ^{18}F-FDG-Trained Deep Kernel Model
Siqi Li

9:30 **MIC-18-03**
List-mode PET Image Reconstruction with Neural Radiance Fields
Haoyu Lu, Haoyu Lu

9:45 **MIC-18-04**
Dynamic image reconstruction for high-resolution SAVANT scanner using non-negative low-rank constraint
Yassir Najmaoui

10:00 **MIC-18-05**
A Generalized Tuy-Type Completeness Analysis for X-Ray Scattering Tensor Tomography
Ruifeng Liu

10:15 **MIC-18-06**
Hamiltonian Monte Carlo Ensemble Features for DATSCAN SPECT Analysis in Parkinson's Disease
Theodoros Leontiou

10:30 **MIC-18-07**
Monte Carlo–based reconstruction in Ac-225 SPECT: impact on image quality, quantitative accuracy, and computational burden.
Chenguang Li

10:45 **MIC-18-08**
Sparse-View ^{177}Lu SPECT Reconstruction for Pre-Treatment Dosimetry using Gaussian Mixtures
Hyun Ji Lee

9:00 – 11:00 MANUEL DE FALLA
MIC-19 Signal and data processing

Chairs:
Jae Sung Lee (Seoul)
Fumio Hashimoto (Gainesville)

9:00 **MIC-19-01**
Noise-Aware Brownian Bridge Diffusion Model for Denoising of Low-Dose PET Images
Wolf De Mits

9:15 **MIC-19-02**
N2N-DiffPET: Self-supervised Diffusion for Low-dose PET Image Denoising
Quanzheng Li

9:30 **MIC-19-03**
Multi-Dose PET Image Denoising using Consistency Flow Matching
Joo Hyun Lee

9:45 **MIC-19-04**
High-Temporal-Resolution Data-Driven Respiratory Motion Estimation in Cardiac PET Imaging
Chen Sun

10:00 **MIC-19-05**
Spatial-variant fast non-linear energy calibration for a high resolution SSLE pixelated PET detector
Lidia Jiménez Algarra

10:15 **MIC-19-06**
Random Coincidence Correction for Inter-Crystal Scatter Events in PET
Hyeongseok Shim

10:30 **MIC-19-07**
A Software-Based Coincidence Sorters for Simultaneous PET Emission and Lu-176 Intrinsic Transmission Data Extraction
Xin Zhao, Xin Zhao

10:45 **MIC-19-08**
Characterisation of Positron Emission Particle Tracking (PEPT) Performance for In-vivo Blood Flow Estimation in Preclinical PET
Laurence Vass

11:30 – 12:45 FEDERICO GARCÍA LORCA
MIC-20 Total body imaging systems including applications and kinetic modeling, molecular connectivity and radiomics

Chairs:
Stefaan Vandenberghe (Ghent)
Kevin Chung (Boston)

11:30 **MIC-20-01**
Evaluation of Sparse-Geometry Designs for Long-Axial Field-of-View Preclinical SPECT
Elissa L. Avila

11:45 **MIC-20-02**
Feasibility study of ^{68}Ga/^{18}F multiplexed PET imaging on a total-body PET scanner
Wen He

12:00 **MIC-20-03**
Positronium Lifetime Imaging on LAFOV PET: Impact of Estimation Methods and Count Statistics
Lukas U. Rauscher

12:15 **MIC-20-04**
Intercept Graphical Plot with Normalization for Total-Body PET Parametric Imaging with Reduced Input Function Data and Enhanced Inter-Subject Quantification
Yiran Wang

12:30 **MIC-20-05**
Generative Consistency Model for Bayesian Kinetic Model Selection in Dynamic Total-Body PET
Yun Zhao

11:30 – 12:45 MANUEL DE FALLA
MIC-21 Theranostics, Imaging and dosimetry in therapy (particle, radiopharmaceutical, surgery) (2)

Chairs:
Youngho Seo (San Francisco)
Andrea Gonzalez Montoro (Valencia)

11:30 **MIC-21-01**
Experimental System Performance Characterization of Alpha-SPECT and Exploration of Angular Sampling Enhancement via Collimator Micro-Rotation
Shubham Mandot

11:45 **MIC-21-02**
First Validation of a BNCT-SPECT System Based on a Detector with Embedded AI in a Clinical-Like Facility
Tommaso Ferri

12:00 **MIC-21-03**
Imaging of TAT in Clinical Phantoms with a CZT Compton Camera
Biswajit Das

12:15 **MIC-21-04**
Design of a PET&SPECT shared Detector with Low- and Medium-Energy Scintillator-as-Collimator for Lu-177 Imaging
Xiangtao Zeng

12:30 **MIC-21-05**
Dosimetry Evaluation Studies in Non-Melanoma Skin Cancers Using a Novel Thin-Layer Scintillation Detector
Giulia Tosetti, This project has received financial support from the CNRS through the MITI interdisciplinary programs.

12:45 – 13:05 FEDERICO GARCÍA LORCA
MIC-22 Closing

Chairs:
Vesna Sossi (Vancouver)
Roger Fulton (Sydney)

9 November, 2026

15:00 – 17:00 ANDALUCÍA II & III
RTSD-01 RTSD Opening

Chairs:
Michael Fiederle (Freiburg)
Gerard Arino-Estrada (Barcelona)

15:00 **RTSD-01-01**
Exploring 4x4x3 cm^3 3D-CdZnTe Semiconductor Gamma-Ray Detectors
Zhong He

15:15 **RTSD-01-02**
Visualizing the Hidden Physics of CdTe Detectors: Direct Spatiotemporal Imaging of Charge Clouds
Adriano Cola

15:30 **RTSD-01-03**
Compton Imaging Capability of 1-cm-Thick Pixelated TlBr Detectors
Keitaro Hitomi

15:45 **RTSD-01-04**
Effect of the Anode Irradiation by X-ray on the Polarization of a CdTe Imaging Sensor
Petr Praus

16:00 **RTSD-01-05**
Identification and control of interfacial limits enabling high-performance photon-counting perovskite radiation detectors
Ganbaatar Tumen-Ulzii

16:15 **RTSD-01-06**
High-Z Sensor Characterisation and Readout Development for X-ray Detectors at PSI
Jonathan Mulvey, On behalf of the detector group whose members include:J. Mulvey, M. Anastasi, A. Bergamaschi, M. Brueckner, M. Carulla, R. Dinapoli, S. Ebner, S. Emiliani,K. Ferjaoui, E. Fr¨ojdh, V. Gautam, D. Greiffenberg, S. Hasanaj, V. Hinger, V. Kedych, T. King, S. Li,C. Lopez-Cuenca, L. Lunin, A. Mazzoleni, D. Mezza, S. Moses, K. Moustakas, A. Mozzanica, M. Mueller,C. Ruder, B. Schmitt, S. Silletta, D. Thattil, X. Xie and J. Zhang

16:30 **RTSD-01-07**
Response of a Timepix4 CdTe spectral imaging detector for radiographic applications
Laura A. Cerbone

16:45 **RTSD-01-08**

Exploring the X-ray imaging with single-crystalline integrated perovskite sensors

Vitalii Bartosh, Vitalii Bartosh

17:30 – 19:00 ANDALUCÍA II & III

RTSD-02 RTSD Aviation Inspection & Security Applications

Chairs:
Zhong He (Ann Arbor)
Jan S. Iwanczyk (Los Angeles)

17:30 **RTSD-02-01**

Next Generation Room Temperature Semiconductor Detectors, Sources, and Methods for Computed Tomography in Aviation Security

William C. Barber, William C. Barber

18:00 **RTSD-02-02**

A new compact prototype for 3D gamma coded-aperture spectro-imaging

Giulia Rosso

18:15 **RTSD-02-03**

Characterization of a miniature prototype photon counting detector system and evaluation of its imaging performance for potential use in threat and explosive detection CT scanners; A new paradigm for security screening.

Georgios Prekas

18:30 **RTSD-02-04**

Tileable Imager Architecture using HiSPECT Gamma Imaging Modules and Applications

Guillaume Montémont, Guillaume Montémont

18:45 **RTSD-02-05**

Activity Quantification Using Experimentally Imaged Source Distributions

Christopher G. Wahl, Christopher G. Wahl

10 November, 2026

9:00 – 11:00 ANDALUCÍA II & III

RTSD-03 RTSD Pixel Detectors

Chairs:
Dominic Greiffenberg (Villigen)
Filippo Mele (Milano)

9:00 **RTSD-03-01**

Flat-Panel Intensity Normalization for Fully Spectroscopic CT-Based Material

Identification with 1 mm CdTe Timepix3 Detectors
Michael K. Schütz

9:15 **RTSD-03-02**
A Pixelated CCl TlBr Detector for Time-Resolved Multi-MeV Gamma Detection
Leonor Rebolo

9:30 **RTSD-03-03**
Self-Consistent Simulation of Charge Sharing in CZT Pixel Detectors
Andrea Zappettini

9:45 **RTSD-03-04**
Waveform-Based Depth-of-Interaction Characterization in 5-mm Cross-Strip CdZnTe
Max Teicheira

10:00 **RTSD-03-05**
Ultra-High Resolution CZT Gamma Camera Using Machine-Learning Based 3D Interaction Localisation
Alexander Cherlin

10:15 **RTSD-03-06**
Optimized femtosecond laser ablation processing of hybrid semiconductor detectors for enhanced spectroscopic and imaging performance
Zuzana Melnikova

10:30 **RTSD-03-07**
Energy, Spatial and Timing Performance of CZT Drift Strip Detectors
Andrea Zappettini

10:45 **RTSD-03-08**
Circularity-Based Spectroscopic Correction for Small-Pixel CdTe/Timepix Detectors
Elena Maria Zannoni

15:00 – 17:00 Poster Area
RTSD-04 RTSD Poster Session

Chairs:
Michael Fiederle (Freiburg)
Gerard Arino-Estrada (Barcelona)

15:00 **RTSD-04-350**
Characterization of Bremsstrahlung Photon Contamination in Clinical Electron Beams via CdZnTe Detectors
Chansun Park

15:00 **RTSD-04-351**
Engineering Low-Reverse-Current $CsPbBr_3$ Sensor Structures through Surface Passivation and Deposition of Different Contacts
Volodymyr Gnatyuk

15:00 **RTSD-04-352**
Additive Engineering of $Cs_2AgBiBr_6$ Double Perovskite Single Crystals: Growth Optimization, Structural Characterization, and Radiation Detector Evaluation
Nazire S. Sahsuvar

15:00 **RTSD-04-353**
Solution Growth and Material Characterization of $Cs_2AgBiBr_6$ Double Perovskite Crystals for X-Ray Detection: Crystal Quality, Electrical Transport Properties, and Structural Defects
Zeynep Cihan

15:00 **RTSD-04-354**
A new approach for studying phase equilibria in the CdTe-MnTe system
Aleksey Bolotnikov

15:00 **RTSD-04-355**
First Clinical Evaluation of a Gallium Nitride Diode Array for Proton Pencil Beam Scanning
Luisa Parschat

15:00 **RTSD-04-356**
An Integrated Purification-Growth Strategy for High-Performance Perovskite $CsPbBr_3$ Crystals
Junfeng Chen

15:00 **RTSD-04-357**
Spectral Performance of GaAs:Cr Photon-Counting Detectors with Various Thicknesses
Boren Wang

15:00 **RTSD-04-358**
Optical manipulation of space charge in rectifying CdZnTe/CdTe radiation detectors
Samuel Kačenga

15:00 **RTSD-04-359**
High-Voltage Tolerant Ni/YSZ/4H-SiC MOS Detectors for Thick Active Layers
Marcel Talacko

15:00 **RTSD-04-360**
Polycrystalline Based Semiconductors (PBS) TlBr for High Energy X-ray Detection and Radiography
Jarek Glodo

15:00 **RTSD-04-361**
Lateral Expansion of the Active Region in Semi-Insulating GaAs Radiation Detectors with Different Schottky Contact Sizes
Nikola Kurucova

15:00 **RTSD-04-362**
Depth-Resolved Measurement of Charge-Cloud Formation and Transport in a 2.0 mm CdTe-Timepix3 Detector
Duarte S. Rodrigues

15:00 **RTSD-04-363**
When 0 V Is Not Really 0 V: Remnant Fields in $MAPbBr_3$ X-Ray Detectors
Jean-Marie Verilhac

15:00 **RTSD-04-364**
Vibration-suppressed solution growth of perovskite single crystals for high-resolution gamma-ray detection
Haodi Wu

15:00 **RTSD-04-365**
Investigation of the anisotropy of the electronic properties of $CsPbBr_3$
Aleksey Bolotnikov

15:00 **RTSD-04-366**
Controllable Fabrication of High-performance Perovskite Single Crystals in Solution toward Efficient X-ray Detection
Yu Chen

15:00 **RTSD-04-367**
Improved Stability of Perovskite Single Crystal Semiconductor X-ray Detector via 2D Layer Formation
Dakyoung Lee

15:00 **RTSD-04-368**
Highly Radiation-Hard Flexible Perovskite Imaging Arrays for Real-Time Proton Beam Monitoring
Yang Zhang

15:00 **RTSD-04-369**
FAPbBr3 Single Crystal Perovskite Radiation Detector with Embedded Electrode Array Architecture
Seán Cardiff

15:00 **RTSD-04-370**

15:00 **RTSD-04-371**
Evaluation of carrier transport properties of TlBr semiconductor detectors
Kenichi Watanabe

15:00 **RTSD-04-372**
Fabrication of Flexible Nanostructured Polymer for Nanomaterial-based Detectors
Ill-Hyuk Han

15:00 **RTSD-04-373**
Enhanced Imaging Uniformity of Perovskite X-ray Detectors via Combined Uniform Particle Dispersion and Solution-assisted Hot Pressing Treatment
Xulong Pang

15:00 **RTSD-04-374**
Investigation of Metal Oxides as Contact Materials for CdTe X-Ray, Gamma-Ray Detectors
Madan Niraula

15:00 **RTSD-04-375**
Transport Properties of CdTe Semiconductor after Laser Ablation
Jakub Dřevo

15:00 **RTSD-04-376**
Contact Characterization of High-Flux Stable GaAs:Cr Detector
Boren Wang

15:00 **RTSD-04-377**
Validation of FAPbBr3 Perovskite Radiation Stability: Monte Carlo Simulation and Proton-Irradiation Experiment
Zeqi Huang

15:00 **RTSD-04-378**
CZT Strip Detectors Characteristics After the Euro Material Ageing Mission
Andrea Zappettini

15:00 **RTSD-04-379**
Development of a Compact CdTe-Based Gamma Spectroscopy System with Dual-Side Readout for High-Resolution Gamma Imaging
Siyao Chang

15:00 **RTSD-04-380**
An Event Reconstruction ASIC for 3D CdZnTe Gamma-Ray Detectors
Farah Mohammed Rafee

15:00 **RTSD-04-381**
Spectroscopic Performance of SOI-CMOS Pixel Detector at Elevated Temperatures
Haruno Takamoto

15:00 **RTSD-04-382**
Development of Zero-Grid-Bias Operation in Coplanar Grid Type TlBr Detectors
Seishiro Tanaka

15:00 **RTSD-04-383**
A Monte-Carlo Simulation of Unipolar Charge-Sensing Amorphous Selenium X-ray Detector for Photon Counting Imaging
Arev Koc

15:00 **RTSD-04-384**
Study of the spectroscopic performance of Timepix4 with highly ionizing particles
Petr Smolyanskiy

15:00 **RTSD-04-385**
Investigation of Gain Instability of a 3-D CdZnTe Detector
Matthew Granados

15:00 **RTSD-04-386**
Bias Scan Analysis of Si-Timepix Detector with Various Sensor Thickness
Andrea Sagatova

15:00 **RTSD-04-387**
Multidimensional Parameter-Space Analysis of Fast Neutron-Induced Tracks in Timepix Detectors
Matej Balušík

15:00 **RTSD-04-388**
A 512 × 256 a-IGZO Dual-Gate TFT 2T-APS Array for Low-Dose Direct-Conversion X-Ray Flat-Panel Detector
Yihong Qi

15:00 **RTSD-04-389**
Development of a Self-Triggering Pixelated TlBr Detector with Cherenkov Light Detection
Tsubasa Komaki

15:00 **RTSD-04-390**
Readout Electronics of SPECTRE CZT detector
Damanio Cabiati, On behalf of SPECTRE Collaboration

15:00 **RTSD-04-391**
Spectral Response and Counting Characteristics of a Peak-finding ASIC for GaAs:Cr Detectors
Xiaochun Lai

15:00 **RTSD-04-392**
Thickness-dependent front-end noise in CdTe Timepix3 detectors
Juan S. Useche Parra

15:00 **RTSD-04-393**
SiC Timepix3 detector response to fast neutrons: effect of varying sensor bias
Katarina Foss

15:00 **RTSD-04-394**
A neural network determining the gamma interaction position in pixelated CZT detectors
Adeiza S. Anumah

15:00 **RTSD-04-395**
Robust and reliable radionuclide identification under realistic measurement conditions
Andrea Zappettini

15:00 **RTSD-04-396**
In-situ high-resolution gamma spectroscopy for characterization of radiological environmental sites.
Bertrand Rossé

15:00 **RTSD-04-397**
Gamma Spectroscopy Analysis and Benchmarking of Nuclear Fuel for Next Generation Reactor Designs
Daryl T. Giglio

15:00 **RTSD-04-398**
Comparison of the simulated response of the in-house DT hybrid pixel detector with synchrotron beam tests
Mélissa Leroy

15:00 **RTSD-04-399**
Characterization and Compensation of Radiation-Induced Leakage Current in CdTe/CZT Detectors Under High-flux X-ray Irradiation
Xinchi Ran

15:00 **RTSD-04-400**
Compton Polarimetric Potential of a Low Power CdTe Timepix3 Frame Mode Detector
Duarte Rodrigues

15:00 **RTSD-04-401**
Imaging Performance Comparison of a GaAs Photon-Counting Detector and an Energy-Integrating Detector under Various Photon-Flux Conditions
Boren Wang

11 November, 2026

9:00 – 11:00 ANDALUCÍA II & III
RTSD-05 RTSD Perovskite Detectors

Chairs:
Andrea Zappettini (Parma)
Paul Sellin (Guildford)

9:00 **RTSD-05-01**
Performance Improvements on Perovskite Gamma-Ray Detectors Using Depth-Dependent Shaping Optimizations
Max Robbins

9:15 **RTSD-05-02**
On Technological Aspects In The Development Of Perovskite Gamma Radiation Detectors
Normunds Grundmanis

9:30 **RTSD-05-03**
Metal-Halide Perovskites for Fast Hard-Radiation Detection
Anastasiia Sakhatska

9:45 **RTSD-05-04**
Growth of $MAPbBr_3$ Single Crystals for X-Ray, Gamma Ray Detection by Slow Solvent Evaporation at Room-Temperature
Madan Niraula, Madan Niraula

10:00 **RTSD-05-05**
Millimeter-Thick Perovskite Single-Crystal X-ray Detectors with Unity Charge Extraction

in Photovoltaic Mode
Kostiantyn Sakhatskyi

10:15 **RTSD-05-06**
Multipixel 2D Perovskite Thin-Film Array for High-Resolution Proton Beam Profiling
Ilaria Fratelli

10:30 **RTSD-05-07**
Phase-Pure Orthorhombic $CsPbBr_3$ Perovskite Materials for Low-Lag, Ultrahigh-Resolution Direct X-ray Detectors
Shariar Motakef

11:30 – 13:00 ANDALUCÍA II & III
RTSD-06 RTSD Perovskite Detectors II

Chairs:
Juan S. Useche Parra (Freiburg)
Ge Yang (Raleigh)

11:30 **RTSD-06-01**
Influence of the Active Layer Thickness on the Performance of Metal-Halide-Perovskite Thin Films for X-ray Detectors
Marco Girolami

11:45 **RTSD-06-02**
Optimization of $FAPbBr_3$ Single Crystals for Photon Counting Radiation Detection
Paul Sellin

12:00 **RTSD-06-03**
Transient Currents in 4H–SiC Radiation Sensors with Graphene Electrodes
Eduard Belas

12:15 **RTSD-06-04**
Perovskite $CsPbBr_3$ Cherenkov charge induction gamma-ray detector with sub-ns timing resolution
Lei Pan

12:30 **RTSD-06-05**
Unraveling Atmosphere-Dependent Trap-Mediated X-Ray Detection in Organic Field-Effect Transistors
Giulia Napolitano

12:45 **RTSD-06-06**
Li- and B-Doped $CsPbBr_3$ Composites for Fast Radiation Scintillation Detection
Mohamed Boukhicha

15:00 – 17:00 ANDALUCÍA II & III
RTSD-07 RTSD Pixel Detectors II

Chairs:
Krishna C. Mandal (Columbia)
Chris G. Wahl (Ann Arbor)

15:00 **RTSD-07-01**
Physics-Informed 3D Gaussian Splatting for Multi-View Compton Camera Imaging
Rui Ma

15:15 **RTSD-07-02**
Benchmark of the H3DD_UMv5 Waveform Sampling ASIC for Pixelated Room-Temperature Semiconductor Detectors
Yuefeng Zhu

15:30 **RTSD-07-03**
Optimizing Array Configurations of Position-Sensitive Virtual Frisch-grid Detectors for Coded Aperture Telescopes
Aleksey Bolotnikov

15:45 **RTSD-07-04**
Measurement of the energy response function of a photon counting prototype detector using the HEX-27 beamline at the Brookhaven National Laboratory; A method to derive an empirical model of the detector non-ideal behavior and to improve material discrimination by spectrum deconvolution.
Georgios Prekas

16:00 **RTSD-07-05**
3D Integration and Interconnects for the Readout of Hybrid Pixel Detectors
Francisco Piernas Diaz, On behalf of the Medipix Collaboration and the EP R&D Work Package 5.

16:15 **RTSD-07-06**
Carrier Dynamics and Polarization in GaAs:Cr Detectors Under High X-ray Flux
Boren Wang

16:30 **RTSD-07-07**
Evaluation of Cr-Compensated GaAs Sensors with Different Thicknesses by Photon-

Counting ReadoutElectronics
Juha Kalliopuska

17:30 – 19:00 ANDALUCÍA II & III
RTSD-08 RTSD Medipix/Timepix Detectors

Chairs:
Amlan Datta (Natick)
Christer Frojdh

17:30 **RTSD-08-01**
The Timepix ASIC Family: Past, Present, and Future
Rafael Ballabriga, On behalf of the Medipix2, Medipix3 and Medipix4 Collaborations

18:00 **RTSD-08-02**
Timepix4 based photon-counting detector for full-spectral X-ray micro computed tomography
Paolo Cardarelli

18:15 **RTSD-08-03**
Machine learning pipeline for spectral material identification with a CdTe-Timepix3 detector
Juan S. Useche Parra

Short Courses

7 November, 2026

Time:
7 November, 2026
9:00 – 18:00

Room:
Alhamar @Hotel Saray Granada

SC-01 | Front-End Electronics for Radiation Detectors

Material for preparation can be downloaded here

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

Successful front-end electronics developments emerge from tight collaboration between electronics engineers and specialists in detectors, data acquisition, and system integration. This one-day short course delivers the core concepts required to understand front-end design, enabling clearer communication and more effective interdisciplinary teamwork.

The course is ideal for both seasoned engineers and those new to the field—circuit designers, physicists, and detector specialists alike—providing a solid foundation in low-noise front-end circuit design. Participants will actively work alongside the instructor on practical examples of noise analysis, circuit design, and simulation. **Attendees must bring a laptop with the required software pre-installed** (see the instructions in the attached document - yellow button "Material for preparation can be downloaded here").

The final segment explores in depth a topic of broad interest to the NSS-MIC community: radiation tolerance.

Outline

Part I: Fundamentals – Gianluigi De Geronimo

- Noise sources and equivalent noise charge
- Noise analysis in frequency domain
- Interactive noise analysis, design and simulations

Part II: Fundamentals – Gianluigi De Geronimo

- Noise analysis in time domain
- Charge amplifier design
- Interactive noise analysis, design and simulations

Part III: Fundamentals – Gianluigi De Geronimo

- Filter design
- Mixed-signal circuits
- Waveform sampling and digitization
- Interactive noise analysis, design and simulations

Part IV: Radiation Tolerance – Lodovico Ratti

- Introduction: radiation environments and radiation sources
- Ionizing radiation effects on MOSFET transistors
- Ionizing radiation effects: from low to extreme doses
- Ionizing radiation effects: from bulk CMOS to finFETs

Instructor's Biographies

Gianluigi De Geronimo received his M.S. and Ph.D. in Electronics from Politecnico di Milano, Italy. He joined the Instrumentation Division at Brookhaven National Laboratory (BNL) shortly thereafter, where he specialized in the design of low-noise integrated circuits for ionizing radiation detectors. Over his career at BNL, he advanced from Assistant Scientist to Tenured Scientist and Head of the Microelectronics Group. Dr. De Geronimo has developed numerous high-performance front-end ASICs for applications in medical imaging, space, security, defense, and fundamental physics research. He is the founder of **DG Circuits**, where he continues his work as an independent ASIC designer and consultant. He also serves as Adjunct Professor at Stony Brook University and as an Editor for the IEEE Transactions on Nuclear Science. He has co-authored more than 150 scientific publications and two book chapters, and is the recipient of the 2008 BNL Science and Technology Award, three R&D 100 Awards (2009, 2011, 2014), the 2012 CSIRO Award, the 2012 Battelle Inventor of the Year Award, and the 2018 IEEE Long Island Section Charles Hirsch Award

Lodovico Ratti is Full Professor of Electronics at the University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Italy. His main research expertise lies in front-end electronics for highly segmented radiation detectors, photodetectors (SPADs, SiPMs), and monolithic sensors, particularly those based on CMOS processes. His work also focuses on ionizing radiation effects, bulk damage, and noise characterization in microelectronic devices and circuits. The target applications of his research include high-energy physics, astrophysics, and photon science experiments. Lodovico Ratti serves as Secretary of the Radiation Instrumentation Steering Committee (RISC) of the Nuclear and Plasma Science Society (NPSS). He is also a Technology

Research Fellow with the National Institute for Nuclear Physics (INFN), Italy. He is the author or co-author of more than 360 publications, including peer-reviewed journal papers, conference proceedings, contributions to international conferences, and book chapters. He also serves as editor for IEEE Transactions on Nuclear Science, Frontiers in Physics, and MDPI Electronics.

SC-02 | Analog and digital SPAD-based photodetectors

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Outline

Part I: SPAD physics [Fabrice Retière]
Single Photon Avalanche Diodes (SPADs) are the building blocks of Silicon Photomultiplier (implicitly analog) and digital SPAD array. SPADs operate following several steps: 1.1) transmission (as opposed to reflection or absorption) of photons into the silicon, 1.2) absorption of the photons within the silicon at wavelength-dependent depth, 1.3) production of electron-hole pairs considering quantum yield, 1.4) drift or diffusion of the carrier towards the high field region, 2.1) initiation and evolution of the avalanche, 2.2) quenching, 2.3) production of a detectable signal. SPADs carry a set of undesirable features: 3.) dark noise, 4.) carrier trapping and detrapping yielding to after-pulse, 5.) light production in avalanche yielding to internal and external optical crosstalk. Each item will be discussed in detail.

Part II: Analog SiPMs, timing and read-out (metrology) [Stefan Gundaker]
The silicon photomultiplier (SiPM) has become the standard device in many time-critical applications, ranging from

single-photon detection in quantum cryptography or light detection and ranging (LiDAR) to multi-photon detection in high-energy physics and time-of-flight positron emission tomography. The basic working principles of the SiPM will be introduced, and the most important parameters, such as photon detection efficiency, single-photon time resolution, and noise sources, will be discussed. The front-end electronics, an important aspect of the readout of analog-SiPMs, will be examined, and basic principles will be presented. Furthermore, the impact on SiPM parameters and electronic readout on timing will be explained when applied to scintillation, Cherenkov emission and single-photon detection. Prominent examples of applications will be reviewed, and the possible future of analog-SiPMs will be evaluated.

Part III: Digital SiPMs: Introduction (quenching circuits, metrology) [Serge Charlebois]
Review of various quenching circuit architectures, edge discriminators, and control of the quenching-recharge cycle. Methods to characterize performances adapted to digital SPADs.

Part IV: Digital SiPMs: Architectures and Applications [Claudio Bruschini]
We will provide a short overview of some of the main chip and system architectures which have been explored over the years for SPAD arrays and digital SiPMs, with an eye on the specificities of high-energy and nuclear physics applications. This will be complemented by a brief technology-oriented discussion.

Part V: Demos
We will provide examples of various data output obtained from digital SPAD detectors and demonstrate basic analysis performed on them (e.g., event rate, crosstalk, pulse shape analysis, single-photon timing resolution, coincidence timing resolution). We will also strive at bringing physical demonstrations of digital SPAD detectors.

SC-04 | State-of-the-art semiconductor detectors in basic science, applied science and in industry

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

A solid understanding of the physics and technology underlying semiconductor detectors enables researchers to align experimental measurements more effectively with the scientific questions under investigation. It further facilitates the optimization of data analysis procedures, allowing experiments to approach the intrinsic resolution limits of the measurement setup. Moreover, such knowledge empowers users to formulate well-founded proposals for improving measurement processes in both hardware and software.

This one-day course begins with the fundamentals of semiconductor physics, followed by an overview of the interaction of ionizing radiation with semiconductor materials. Key concepts such as charge carrier generation and transport, basic device architectures, and an introduction to process and device simulation will be covered.

Depending on the application, semiconductor detectors require dedicated electronics characterized by low noise and high speed. Accordingly, noise sources and mitigation strategies will be discussed in detail. The course will

also introduce application-specific integrated circuit (ASIC) developments for signal amplification and data processing, concluding with an overview of state-of-the-art ASIC designs that enable complex detector systems.

Applications of semiconductor detectors across astrophysics, materials science, life sciences, and high-energy physics will be presented, each beginning with a clear motivation and a description of the relevant experimental constraints. In astrophysics, both space-based missions - such as XMM-Newton, Chandra, eROSITA, and BepiColombo - and future projects like ATHENA and LISA will be discussed, alongside ground-based systems employing e.g. adaptive optics.

In materials and life sciences, experiments conducted in institutional laboratories, synchrotrons, and X-ray free-electron lasers rely on electrons, protons, and X-rays to probe for example, crystal structures, molecular bonds, electric and magnetic fields, mechanical stress and many more. These applications impose diverse requirements on detectors, including high dynamic range, spectroscopic imaging capabilities, ultrafast response and count rate capability.

High-energy particle and nuclear physics have historically driven the development of advanced detector technologies. Examples include accelerator-based experiments at CERN, DESY and KEK, as well as underground experiments such as DUNE and GERDA. Recent technology developments lead to record performance (in spatial resolution, timing information resolution, radiation hardness, large area coverage) and to a broad variety of applications extending to astrophysics, beam and dose monitoring in hadron therapy, and more.

The basics of semiconductor physics and technology will be treated in detail. By providing a comprehensive overview of a broad range of applications, the course aims to stimulate new experimental ideas and support students and researchers in refining their experimental scientific research.

Outline

Part I: Semiconductor detector physics – 100 min

Part II: Electronics for semiconductor detectors – 90 min

Part III: Semiconductor detectors in astronomy and astrophysics – 60 min

Part IV: Semiconductor detectors in material and life sciences – 90 min

Part V: Semiconductor detectors in high energy physics – 90 min

Part VI: Summary and discussion – 30 min

Instructors

Lothar Strüder is professor at the University of Siegen. He earned his PhD in Physics at the Technical University Munich in 1988. His major scientific interests include position-, energy- and time resolving detectors for photons and particles. He is author and co-author of more than 500 technical and scientific publications with over 25.000 citations. He holds 15 worldwide patents in scientific instrumentation. Among other awards he received the Glenn F. Knoll Radiation Instrumentation Outstanding Achievement Award of the IEEE in 2019 and became Fellow of the MAS in 2020.

Giuseppe Bertuccio is professor of electronics and head of the Semiconductor Detector and Integrated Circuits Laboratory at Politecnico di Milano, where he began in 1987 in Prof. Emilio Gatti's research group. He has been visiting researcher at Brookhaven National Laboratory and at Canberra Industries, and has collaborated with numerous universities, research centers and companies worldwide on radiation detectors and low-noise electronics for scientific, industrial, and medical applications. He received the 2019 RTSD Scientist Award in recognition of his contributions to the field of room-temperature semiconductor detectors, electronics and systems.

Silvia Masciocchi is professor for experimental particle and nuclear physics at the University in Heidelberg, and head of the ALICE department at GSI, the Helmholtz Center for Heavy Ion Research in Darmstadt. Her research interests include heavy-ion physics and the development of particle detectors, with a particular focus on high precision tracking and vertexing, and on particle identification. After working with silicon strip detectors and with the large-volume Time Projection Chamber in ALICE, she recently moved to the development and integration of monolithic active pixel sensors (MAPS) produced in CMOS technology. Within the Helmholtz Matter program, she is the speaker of the Detector Technology and Systems topic.

Andrew Fram is Product Manager for detector systems at PNDetector GmbH. He has worked with X-ray and electron detector systems for more than eight years, holding product management and technical sales roles. His experience spans OEM instrument manufacturers, synchrotron facilities and research institutions worldwide. He has provided technical input on detector requirements, system configuration and application-specific integrations for energy-resolving X-ray and electron detection systems. His perspective is based on practical work with users, applications teams and engineering groups across the detector-system lifecycle. He holds a BEng (Hons) in Mechanical Engineering Design.

Course and all breaks in Hotel Saray

Description

This course is an introduction on how to get your message across in writing as a physical scientist. We concentrate on refereed papers and proposals/job applications but also touch upon other formats. The course is aimed at beginning scientific writers, PhD students and junior postdocs, but more experienced writers may find many aspects interesting, eye-opening, or simply useful in developing their own writing. The skills learned in this course will be more generally applicable as well, whether or not you not plan to build a further career as an academic.

During the course and the exercises, you will refer to your own writing when we discuss items like title, abstract, introduction, or paragraph and sentence structure, so bring with you your latest paper, whether in early draft form or already submitted to a journal.

Syllabus:

1. Writing in science

Refereed papers are an important vehicle in science, but not the only format where writing is needed. We will start the course by analysing what writing in science is about, and how you can optimise your written products. Among other aspects, we will study the optimum structure of a paper: where and how do you provide the information?

How to transform your scientific results in a story? And how to then write that story in a clear and precise way so you can produce a good paper? How do you put emphasis?

We will analyse how you catch a reader's attention in our current era of information overload, and highlight the importance of title and abstract.

2. How to write your papers?

You will learn to optimally structure your text, from the entire text down to the paragraphs and to individual sentences, thereby writing for the reader. How can topic sentences make paragraphs do their job?

We will highlight grammar rules you need to know so that you will write papers that are pleasant to read as well as correctly written. We will also revise the typesetting conventions that are used in our field, referring to publishers' Instructions for Authors and to LaTeX.

3. How to write a proposal or job application?

Whether you want to get experiment time on a large facility, access to supercomputers, apply for a post-doc position or a prestigious fellowship, get a tenured job, or get funding for your research, you will need to write proposals. And they need to stand out in order to be successful. In this session, you will learn the recipes to follow and the pitfalls to avoid.We will also highlight how you can make and maintain an effective CV, and discuss how you can enhance the effect of your reference letters.

4. How to make optimal use of AI tools?

AI tools, including large language models (LLMs) like ChatGPT or Claude, are revolutionising our lives as scientists. We will consider the advantages and possible pitfalls of the use of AI in preparing your written products, and analyse how you can optimise their use.

This course expands on what we wrote in the following Perspective papers in Nature Astronomy. They are widely applicable across the physical sciences, even though they were specifically written for astronomers. More general papers and books about scientific writing are referenced. We recommend participants to read these three papers before attending the Short Course.

- Chamba et al. 2022: https://rdcu.be/cVdtK How to plan your astronomy research paper in ten steps
- Knapen et al. 2022: https://rdcu.be/cVdtJ How to write and develop your astronomy research paper
- Knapen et al. 2025: https://rdcu.be/evDCt How to prepare competitive proposals and job applications

Instructor

Johan Knapen is a Research Professor at the Instituto de Astrofísica de Canarias in Tenerife, Spain. His research focusses on the structure and evolution of the central regions and the disks of galaxies, combining the exploitation of the sharpest and deepest possible imaging across a range of wavelengths with the use of AI tools. He has published almost 300 refereed papers. He is PI and coordinator of the EU Doctoral Network EDUCADO, and of the EU-funded Twinning network ExGal-Twin. Mentoring and coaching, in particular of young scientists from developing countries, is an increasingly important part of his activities, as is advanced training in scientific writing.

SC-05 | Fast-timing scintillation detectors for medical and other applications

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-19:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

Remarkable progress is being made with regard to the timing performance of scintillation detectors. For example, the time resolution of clinical time-of-flight positron emission tomography (TOF-PET) systems has improved from 500 – 700 ps FWHM in the second half of the 2000s to less than 200 ps FWHM for the latest available systems. In the laboratory, coincident detection of annihilation photon pairs with a time resolution better than 50 ps FWHM has been demonstrated. These advancements are driven by innovations in scintillation materials, photosensors, readout electronics, detector design, and signal processing. In addition to medical imaging, the results of these developments are used in many other domains, such as materials science, nuclear physics, and high-energy physics.

The improvement of scintillation detector time resolution requires the optimization of the full detection chain. A sound understanding of the underlying physics and statistics greatly facilitates such efforts. Therefore, a substantial part of the course will be devoted to the theory of scintillation detector time resolution. It will be shown how the

physical limits of time resolution are governed by scintillation photon counting statistics and, as such, by fundamental properties of the scintillator (e.g. its light yield and pulse shape) and the photosensor (e.g. its photodetection efficiency and single-photon time resolution).

Based on the insights offered by this analysis, we will study the history, state-of-the-art, and ongoing developments in scintillation materials, photosensors, readout electronics, and signal processing. Special attention will be paid to detectors based on silicon photomultipliers (SiPMs), as the introduction of this new light sensing technology is a key driver of time resolution improvement in TOF-PET. Attention will also be paid to the increasing importance of detector design, which affects the kinetics of scintillation photon transport, as well as on the possibilities to mitigate the resulting loss of time information though the concept of time resolution recovery.

SC-06 | Medical predictions from imaging with machine learning: The implementation gap

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

This course addresses the question of why so few machine learning (ML) systems for medical decision-making go beyond proof-of-concept to implementation. In doing so we take the scenic route, first discussing frequentist and Bayes statistical methods that are already successfully deployed with imaging in research and clinical contexts, and the estimates they make that are useful, and how this information is communicated in a way that improves the patient's experience. We then take an introductory tour of statistical learning theory (SLT), arguably the first and most comprehensive framework for ML developments including supervised, unsupervised, and reinforcement learning, and how SLT has been applied to imaging data. Validation and performance testing is an important component to these systems, and after describing the primary techniques, we also discuss contemporary alliances of ML with statistical inference. Finally, we explore the technical, ethical, and organisational reasons why ML systems are particularly absent from routine healthcare, even though they appear to offer an empirical advantage.

Outline

Part I: Statistical testing for medical imaging

- Images as an ordered dataset
- Frequentist and Bayes statistical approaches for imaging
- Including spatial information in test statistics
- The reproducibility crisis and response

Part II: An introduction to Statistical Learning Theory

- Preliminaries
- Components of a ML system
- Cross-validation
- Statistical Agnostic Learning

Part III: The implementation gap

- Technical – the right outputs for the right questions
- Ethical – bias, privacy, and explainability
- Organisational – agency and responsibility, interacting with electronic health records, integration into healthcare processes

Instructors

- John Suckling, niversity of Cambridge
- Subati Abulikemu, Univerysity of Cambridge)

SC-07 | Medical Image Reconstruction: from Foundations to AI

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

Using the primary example of positron emission tomography (PET), core image reconstruction methods will be explained, from unregularised to regularised methods, through to kernel-based and generative AI-based image reconstruction. The coverage of reconstruction and deep learning principles will also touch on implementation aspects for core methods as well as state of the art methodology.

Image reconstruction foundations

- Reconstruction basics: object representation and forward models
- Maximum likelihood expectation maximisation (MLEM)
- Maximum *a posteriori* EM (MAPEM)
  - Priors

- Algorithms

AI for image reconstruction: introduction

- Basic principles of deep learning
- Direct methods (CNNs and CEDs)
- Unrolled iterative deep-learned methods (e.g. FBSEM-Net)
- Methods without training data

Kernel and deep image prior methods

- Conventional kernel EM (KEM)
- Deep image prior (DIP)
- Kernel methods with deep learning

Generative AI for image reconstruction

- Overview of generative models for inverse problems
- Diffusion models and integration with PET image reconstruction
- Unsupervised and supervised approaches

Test-time adaptation: steerable diffusion and deep diffusion image prior

Instructors

- Andrew Reader, King’s College London
- George Webber, King’s College London
- Siqi Li, UC Davis

Time:
10 November, 2026
9:00 – 18:00

Room:

SC-08 | Fundamentals of Total-Body PET

Schedule

08:00-09:00 Breakfast & Registration
09:00-11:00 Part 1
11:00-11:30 Morning Coffee
11:30-13:30 Part 2
13:30-14:30 Lunch
14:30-16:00 Part 3
16:00-16:30 Afternoon Coffee
16:30-18:00 Part 4

Location

Course and all breaks in Hotel Saray

Description

This course focusses on the unique features of Total-Body and long axial field-of-view PET (TB-PET) systems that an imaging scientist needs to know to extract optimal performance from such systems, along with the clinical and research applications enabled by this technology. Participants will explore challenges and solutions for managing the QC, image reconstruction and data processing of TB-PET systems, and how to exploit their unique advantages in a range of applications.

WS-01 | AI in Nuclear Sciences and Nuclear Medical Imaging – Review and future expectations (onsite only)

Chairs:

Jean-Baptiste Michaud (Sherbrooke)
Francis Loignon-Houle (Valencia)

Summary

In many nuclear sciences and medical imaging applications, AI has come a long way and in some instances it has (almost!) become the gold standard. The workshop will outline the major milestone in the last 10 years, the current hot topics and issues, and discuss where future breakthroughs could come from and what our collective priorities should be for the next 10 years.

Contacts

- jean-baptiste.michaud@usherbrooke.ca
- floignon@i3m.upv.es**Panelists** (in alphabetical order)

Irène Buvat

Irène Buvat, PhD, is a Senior researcher at CNRS, and Head of the IRIS lab at Institut Curie, Orsay, France. She obtained her PhD degree in “Nuclear and Particle Physics” from Paris Sud University, France, and focused her research on applications of physics to medical imaging. She is currently the head of the Imaging, innovative Radlation therapy and Systems medicine (IRIS) lab at Institut Curie in Orsay, France. Her research interests focus on the use of positron emission tomography (PET) to understand biological mechanisms involved in cancer and optimize patient management, using multi-scale and multimodal data analysis powered by artificial intelligence (AI). She is highly involved in radiomics and AI research to enhance the role of medical imaging in precision medicine. Her lab has developed the user-friendly LIFEx software to facilitate reproducible radiomic studies (>10,000 users

worldwide). In 2020, she introduced a novel PET biomarker for measuring the dissemination of cancer, that has now been validated in thousands of patients and is commercially available. She promotes open-access to state-of-the-art research material (GATE, LIFEx) and resource sharing to accelerate the development and validation of AI-based methods. She is a member of the SNMMI AI task force and an Associate Editor of the Journal of Nuclear Medicine.

Marco Carminati

Marco Carminati (B.Sc. 2003, M.Sc. 2005, Ph.D. 2010) is currently an Associate Professor of Electronics at Politecnico di Milano (Italy) and Associate with INFN where he coordinates the KATRIN_TRITAN experiment on neutrino physics. His research interests include sensors, low-noise electronics, radiation detectors and nuclear instrumentation for medical imaging, with increasing interest in analog implementations of machine learning for in-sensor processing. He has authored 400+ publications, 6400+ citations, holds 7 patents, and received 3 IEEE Best Paper Awards. He is Senior IEEE member, Chair of the IEEE NPSS Italy Chapter and a Member-at-Large of the NPSS RISC Technical Committee.

Audrey Corbeil Therrien

Audrey Corbeil Therrien is an Associate Professor in the Department of Electrical and Computer Engineering at the Université de Sherbrooke in Québec, Canada. She currently holds the Tier-2 Canada Research Chair in real-time embedded intelligence for ultra-high-rate detectors. Her research aims to improve real-time analyses at the edge with the integration of machine learning in high performance radiation instrumentation systems. These systems can generate hundreds of gigabytes per second and more. Reducing that data at the edge within the detector greatly improves the efficiency of instruments, including high precision medical scanners and dark matter detectors.

Luca Presotto

Luca Presotto is associate professor of applied physics at the University of Milano-Bicocca (Milano, Italy) department of physics. He has previously worked for more than 10 years in the nuclear medicine unit of Ospedale San Raffaele. He served a quick stint as senior PET scientist in IXICO, a contract research organization devoted to brain imaging. His current research interests include image reconstruction and AI-based image analysis. He is part of the scientific board of the Milan Centre for Neuroscience. Also his teaching duties focus on the application of AI in medical imaging. In neuroscience, he has mostly worked in studying neurodegenerative diseases (especially Alzheimer's and Parkinson's disease) using FDG-PET and other tracers targeting amyloid proteins. He has participated in more than 40 scientific publications for which he curated the automated image analysis, accumulating more than 1700 citations.

Ye Qing

Dr. Qing Ye has been leading PET kinetic modeling research and development at United Imaging Healthcare since 2020. She has played a key role in the development and release of multiple AI-based advanced imaging applications. Her research focuses on dynamic and parametric PET imaging, motion correction, and quantitative PET reconstruction, bridging cutting-edge imaging methodologies with clinical applications. Dr. Ye is also an active contributor to the scientific community, having authored or co-authored more than 30 scientific publications.**Panel Moderators**

Francis Loignon-Houle

Francis Loignon-Houle, PhD, is a postdoctoral researcher at the Institute for Instrumentation in Molecular Imaging (i3M) in Valencia, Spain, a joint center of the Spanish National Research Council (CSIC) and the Universitat Politècnica de València (UPV). He obtained his PhD degree in Radiation Sciences and Biomedical Imaging from the Université de Sherbrooke, Canada, and focused his research on instrumentation for positron emission tomography (PET), in particular on the fundamental limits of timing resolution in scintillation detectors. He has contributed to the development and characterization of several organ-dedicated and high-resolution PET scanners, to machine learning–based waveform analysis, and to time-of-flight (TOF) PET image reconstruction. He is

currently working on improving both timing and positioning in new TOF-PET detectors, exploiting Cherenkov emission in BGO with scalable ASIC-based readout electronics and developing machine learning methods for interaction positioning.

Jean-Baptiste Michaud

Jean-Baptiste Michaud is professor of Electrical and Computer Engineering at the Université de Sherbrooke (Quebec, Canada) and an interdisciplinary research leader in artificial intelligence (AI), with prior experience in cutting-edge industrial R&D. For more than twenty years, he has been developing electronic and software technologies, data analysis methods, and AI algorithms for health applications. His contributions center on three collaborations: bra-based breast cancer detection, predictive modeling in the intensive care unit, and medical imaging instrumentation. He provides the vision and technical expertise that drive the resulting biomedical advances. He holds or has filed patent applications in each of his projects, all of which involve a partner company for commercialization, and he also contributes to clinical and preclinical trials within them.

WS-01-01

Kolmogorov-Arnold Networks: A New Paradigm for Explainable Prediction

M. J. Neuer (1,2), I. Garmaev (1)
1 RWTH-Aachen University
2 innoRIID-Ametek, Düsseldorf

In 1957, the findings of Kolmogorov and Arnold showed that continuous multivariate functions can be represented by combinations of simpler, univariate functions. Based on this work, Liu et al. [1] presented in 2024 a novel architecture for formulating neural networks — the Kolmogorov-Arnold network (KAN).
The paper will first introduce shortly the basic foundations of KAN, including how to design, train and apply them. Their structure differs from common multilayer perceptrons (MLP) because KANs train univariate functions on the edges of the network graph. In these functions, typically B-splines, instead of training weights like a MLP, KANs train the control coefficients of the splines. Nodes of the network consequently act as pure transfer points of the internal data. An advantage of this new network type is intrinsic explainability. After training, the splines on the edges represent human-interpretable mathematical functions. They can be visually studied to understand the decision logic within the network. The paper will also show the conversion of a KAN into an symbolic expressions. Secondly, several emerging KAN applications will be reviewed and compared to existing classical machine learning solutions. KANs have already been successfully applied to industrial problems, including cancer screening [2], mechanical predictions [3], time-series prediction [4], bioinformatics [5], soft-sensor solutions [6] andhyperspectral image classification [7]. These recent works show the potential of the approach for application to radiation detection, nuclear security and safety, as well as nuclear medicine.
The present paper will provide a brief outlook on how to use KAN for gamma spectroscopy. One canonical scenario — the differentiation of special nuclear material like weapon-grade plutonium (WGPu) and enriched uranium (HEU) from masking nuclides like iodine (I-131) or gallium (Ga-67, Ga-68) — is used to illustrate thebenefits of the new approach.

WS-01-02

AI at the Front End: Machine Learning for Raw-Signal Processing in Semiconductor Detectors

A. Cherlin, N. Atkins, M. Exley, T. Winterbottom
Kromek Ltd., County Durham, UK

Over the past decade, ML (machine learning) methods in nuclear detection and medical imaging have advanced most rapidly at the back end of the processing pipeline, i.e. enhancement, correction and interpretation of already reconstructed images and spectra. In medical imaging, deep learning is now widely used to suppress noise, automate lesion segmentation, reduce patient dose and scan time, and flag abnormalities to support diagnostic decisions.
However, ML application at the front end of low-level detector signal processing remains comparatively underexplored, even though the conversion of raw detector signals into event information significantly affects all subsequent steps. This review focuses on this stage, with particular attention to room-temperature semiconductor detectors, such as CdZnTe (CZT).
Detector performance has traditionally been improved through theoretical and phenomenological modelling, extensive calibrations and, often, costly hardware modifications such as reducing pixel size to improve position resolution. The review outlines how ML is changing this landscape: models trained on raw detector signals can estimate energy, position and timing significantly more accurately than current signal processing methods, reducing the need for major hardware upgrades.
The underlying ground truth of individual events cannot be measured directly, and characterising every detector in a real system in full detail is usually impractical. Such models therefore rely heavily on simulated training data, which can further be supplemented by experimental data. One of the central challenges is thus the gap between simulation and reality: real detectors exhibit material non-uniformities operating-condition drift, and other effects that simulations and calibrations usually do not fully capture. This review presents strategies reported to date for closing this gap: from generating more representative training data to adapting models to real measurements. These include the authors' recent results, which show that incorporating realistic calibration variations into simulated training data reduces the domain shift between simulated and real data and improves downstream

spectral and image reconstruction. The review concludes with practical considerations for deployment, including real-time implementation and its impact on system performance.

WS-01-03

Edge-AI with CMOS In-Memory Computing for Radiation Detector Acquisition Chains

M. Ronchi, M. Pandocchi, M. Amadori, M. Carminati, G. Borghi, C. E. Fiorini
Politecnico di Milano, Dipartimento di Elettronica, Informazione e Bioingegneria, Milan, Italy
Istituto Nazionale di Fisica Nucleare (INFN), Sezione di Milano, Milan, Italy

We propose a review of digital and analog edge-AI in-memory computing (IMC) solutions for nuclear and medical imaging acquisition chains, with a focus on CMOS based approaches. We start by covering the motivation and historical context for IMC, driven by the von Neumann bottleneck, and its growing relevance to nuclear physics applications as high-density pixel detectors and high-luminosity, high-rate experiments push data-bandwidth demands higher. We then present the two main hardware directions pursued in the field: emerging non-volatile memory devices (memristors, phase-change memory, etc.) versus CMOS/SRAM-based IMC, comparing their trade-offs in maturity, reliability, and PDK availability. We survey how research groups across the nuclear field are approaching edge-AI implementation. We will then present a case study, that is our analog neural network ASIC (ANNA), an in-memory CMOS accelerator designed to be embedded in the analog front-end of Anger-camera PET/SPECT detectors. We briefly detail the initial ANNA V1 proof of concept and the ongoing ANNA V2 validation and monolithic crystal demonstrator. We discuss the advantages and disadvantages we observed with capacitive-based analog computing and the main difficulties encountered. We discuss figures of merit to compare in-memory computing devices, with a focus on energy efficiency (GOPs/W). We close by highlighting the main opportunities and unresolved questions for IMC adoption in nuclear instrumentation going forward. Although studies on the application of these devices to medical imaging and nuclear physics remain limited, we consider this a promising direction for the future of radiation and particle detectors.

WS-01-04

AI in PET: are we ready for more than better images?

I. Buvat
Institut Curie, Paris

Artificial Intelligence is rapidly transforming Positron Emission Tomography imaging. From image enhancement and automated quantification to prognostic models and AI agents, this presentation will explore how AI is reshaping the field. Through selected examples, we will examine what is already clinically available, what still requires extensive validation, and what may come next.

WS-01-05

AI in nuclear imaging and neuroscience: a look at the initial impact

L. Presotto
University of Milano-Bicocca, Italy

In the last decade, the number of medical devices approved for clinical use involving AI has increased exponentially. Most of them are for imaging based applications, due initially to the effectiveness of convolutional neural networks in extracting image features. Translating models into practice opens a large set of challenges, due to "distribution shifts". Such shift are often quite hard to predict and detect before the application is deployed to the end-user setting.
In this review, I will focus mostly on imaging-based neuroscience, a field that developed robust automated analysis algorithms earlier than most others (SPM was released in 1996!). I will select a number of cases of interest to highlight which problems AI can effectively solve and where its inclusion in a full clinical or research pipeline is still suboptimal.

WS-01-06

Lunch Break

WS-01-07

Delegate, Verify, Understand : Agentic AI in the Medical Imaging Research Workflow

G. Bélanger, M. Fromont, J.B. Michaud
Electrical and Computer Engineering, Université de Sherbrooke

Large language models have moved from conversational assistants to agents that can act within a research environment. Operating within a software harness that provides tools and feedback, they read code and data, run analyses, generate figures and revise their work based on what they observe. As these tools evolve rapidly, research groups need to consider how to adopt them in a controlled and transparent manner. Starting from a defined research question, this presentation examines where an agent may contribute at each step of the methodology and how its contribution can be verified. Agents can substantially accelerate tasks that are well established, precisely specified and easily verified, such as implementing known algorithms, standard statistical analyses, data visualization and publication figures, which occupy much of researchers' time. Tasks involving complex reasoning, such as literature synthesis, method selection or new numerical methods, remain possible but require closer supervision and independent validation. Two projects from our group illustrate both regimes. For a deterministic X-ray transport solver, an agent contributed to implementation, optimization and GPU porting, with validation against analytical and Monte Carlo references. For scatter estimation in time-of-flight computed tomography, an agent-assisted literature search led to a well-documented closed-form solution, complemented by active-set methods to enforce non-negativity, replacing our original purely iterative algorithm. Combined with a GPU implementation, this improved accuracy and reduced processing time, for example from about 11 minutes to 0.1 s per projection. Finally, we discuss the risks that accompany these tools. Results obtained with AI assistance should be understood and validated by researchers and reviewed by human peers; how to guarantee this in practice remains an open question.

ALBÉNIZ & MACHUCA

WS-02 | Digital SiPM and SPAD-based sensors (onsite only)

Summary

Digital SiPMs and SPAD-based devices see increased development activity with the potential of improving photon-counting systems. The main NSS program reports on technology performance and application use of available technologies.

The goal of the workshop is to provide a place where upcoming/future technologies can be described by their developers, development roadmaps can be disclosed, and application niches or markets are aimed for.

This is not the type of communication easily accepted in the main program.

To make sure everyone is included, we invite groups who develop digital SPAD systems or have proposals to use this type of photodetectors to contact us for a participation in the workshop.

Tentative topics for the workshop structure:

- Roadmap presented by technology developers (short talks)
- Discussion/debate on collaboration and funding strategies to bring these technologies to use

We will invite spin-offs that commercialize SPAD based detectors to attend the event and participate in the discussion/debate.

This project has received funding from the European Union's Horizon Europe research and innovation programme under grant agreement No 101099896

Abstract
With coincidence timing resolution (CTR) below 100 ps positron emission tomography (PET) with limited angular coverage and even small flat panels could reach state-of-the-art image quality. The PetVision project is developing a novel modular PET detector concept based on high-resolution time-of-flight (TOF) capabilities that approach the physical limits of current scintillator technology.

Achieving this performance requires dedicated development and optimized integration of key PET detector components. We are designing a low noise, high dynamic range frontend electronics, specifically a next generation ASIC with 20 ps intrinsic time resolution and on-chip time-to-digital conversion (TDC). Concurrently, we are advancing SiPM sensor technology to enhance photon detection efficiency and reduce jitter. We also explore 2.5D integration between the photodetector and electronics to minimise parasitic effects and timing dispersion.

This contribution present the project's vision and progress in technology development, focusing on the ASIC design, production of dedicated SiPMs and preliminary tests of 2.5D integration approaches.

WS-02-06

Status of the Picopix project (#3412)

Rafael Ballabriga

Conseil européen pour la Recherche Nucléaire (CERN), Geneva, Switzerland

The presentation is on behalf of the design team: X. Llopart, O. C. Akgun, M. Andorno, R. Ballabriga, G. Bergamin, S. Biereigel, F. Brambilla, A. Caratelli, D. Ceresa, T. Daros, F. De Benedetti, B. Denkinger, A. Fiergolski, V. Gromov, J. Kaplon, S. Kulis, M. Lupi, A. Pulli, S. Scarfi, T. Silva, V. Sriskaran, L. Timmermans, O. Y. Wong

Abstract

PicoPix is a large-area hybrid pixel detector readout ASIC being developed in 28 nm CMOS by CERN and Nikhef. Its main target is the LHCb VELO Upgrade II. It is also aimed at beam loss monitoring and at applications within the Medipix collaboration framework. The design builds on almost two decades of hybrid pixel development in the CERN EP-ESE-ME group. From Timepix (2007, 10 ns time bin) through Timepix3 (2013, ~1.56 ns) and VeloPix (2016) to Timepix4 (2020, 200 ps). PicoPix pushes timing precision into the picosecond regime while keeping fine spatial granularity and very high rate capability.

The chip has a 256 × 384 matrix of 50 µm square pixels and can be tiled seamlessly on three sides, so it can create large detector areas with minimal dead space. It targets a time resolution below 50 ps rms per hybrid (ASIC plus sensor). To survive the extreme radiation environment of the upgraded LHCb VELO, the logic uses triple modular redundancy and is designed for total ionizing doses up to 1 Grad. The chip can handle up to 96 events per 25 ns bunch crossing, which is up to 3.84 × 10^9 events per chip per second. To keep this rate manageable, programmable on-chip data reduction performs event clustering, vetoing, filtering and sorting. Data leave the chip through a data-driven readout over up to four 25.6 Gbps serial links, for a total bandwidth of 102.4 Gbps.

Recent progress in TSV, 2.5D and 3D integration of SiPMs at FBK (#3413)

Alberto Gola

Fondazione Bruno Kessler (FBK), Trento, Italy

Abstract

FBK is developing a set of integration technologies to overcome the limits of wire-bonded, front-side-contacted SiPMs in large-area, high-granularity detectors. We report on the latest progress of our through-silicon-via (TSV) platform. A first run of a glass-less TSV process has been carried out alongside the standard front-side production flow, and the transfer of the process to an external foundry has been assessed. TSVs allow 6x6 mm^2 SiPMs to be

segmented into independently read sub-pixels down to 1 mm^2 on the same die, and a single-cell-access TSV layout, giving back-side access to individual microcells, has been taped out. In parallel, we are pursuing 2.5D and 3D integration with front-end electronics, including 3D stacking of SiPMs on readout ASICs developed with an industrial partner. These approaches enable four-side tileable modules with minimal dead area, and aim at finer segmentation and improved timing for TOF-PET, high-energy physics and space applications.

Status of project PLATON (#3414)

Kodai Kaneyasu[1], **Davide Sgalaberna**[2]

[1] École Polytechnique Fédérale de Lausanne, Neuchâtel, Switzerland; [2] ETH Zurich, Inst. f. Teilchen- und Astrophysik, Zürich, Switzerland

Abstract
The PLATON project is developing scintillator-based detectors for high-resolution particle tracking in applications such as neutrino experiments. This talk presents the development status of PlatonSPAD, a 9 mm × 9 mm sensor fabricated in a 110 nm CMOS image sensor process for single-photon readout in tiled detector modules.
The sensor contains 192 × 160 single-photon avalanche diodes (SPADs) organized into 48 × 40 macro-pixels. Each macro-pixel comprises a 4 × 4 array of SPADs and two event-driven time-to-digital converters (TDCs) with a nominal bin width of 200 ps. The first hit within a macro-pixel triggers timestamp capture and starts a programmable delay. When the delay expires, that macro-pixel latches the states of its 16 SPADs to form a hit map. Each macro-pixel can independently record up to two hit maps per measurement cycle, each paired with its corresponding first-hit timestamp.
Resistively coupled on-chip ring oscillators provide the TDC clocks, and an on-chip phase-locked loop locks them to a nominal frequency of 315 MHz. A selectable buffer chain delays the input reference clock in 70 ps steps, with a maximum delay of 1.12 ns, to compensate for board-level clock skew and align timestamps across tiled chips.

Status of ASPIDES project (#3415)

Tommaso M. Floris[1,2,3], On behalf of ASPIDES-Collaboration

[1] Universita di Pavia, Pavia, Italy; [2] Istituto Nazionale di Fisica Nucleare, Pavia, Italy; [3] Fondazione Bruno Kessler, Trento, Italy

The activity leading to the results presented in this paper was carried out in the framework of the ASPIDES project, funded by the National Institute for Nuclear Physics (INFN), Italy.

Abstract
As part of the ASPIDES collaboration, a prototype of a fully digital SiPM in 110 nm CMOS technology, based on a fast parallel adder and featuring first-photon timing and time-over-threshold measurement capabilities, was submitted in December 2025. The development of a dedicated test board has been completed, and the measurement setup is currently being finalized. Pending the results of the initial experimental characterization, the design of a scalable demonstrator has been initiated. This new version is designed to interconnect multiple digital SiPMs, similar to those currently under evaluation, through a simplified serial input/output interface. This approach minimizes the physical interconnect overhead toward the control FPGA, thereby enabling a single FPGA to manage a considerably larger number of devices.
The digital interface electronics must support two main functions: the configuration of internal structures and the retrieval of data from all integrated modules. The communication process is based upon a 32-bits instruction-based protocol, which enables individual module addressing, thereby supporting SiPM programming and command execution. This protocol includes functions such as pixel reset, acquisition window control, configuration register menagement and control of the output data format. The demonstrator is targeted for completion in spring 2027.

Packing Functionality under SPADs with nanometer scale 3D Stacking Technologies (#3418)

Robert K. Henderson

University of Edinburgh, School of Engineering, Edinburgh, UK

Abstract
This talk will look at recent 3D stacked SPAD sensors and consider the limits of what electronics can be packed under SPAD detectors. In latest 3D stacked nanometer-scale SPAD technologies. We will consider examples of high resolution arrays for HDR intensity imaging, LIDAR arrays and computational pixels for life-science applications. The prospects for the nuclear science community to harness these largely consumer/automotive driven technologies will be discussed.

ASPIDES: a digital SiPM in 110nm CMOS - rationale, technology choice and open challenges (#3419)

Lodovico Ratti, On behalf of the ASPIDES collaboration

Universita di Pavia, Dipartimento di Ingegneria Industriale e dell'Informazione, Pavia, Italy

Abstract
ASPIDES is an R&D project funded by INFN and involving several groups, targeting HEP applications such as dual-readout calorimetry and RICH detectors. It aims at a proof of principle of a fully digital SiPM in CMOS technology, where photon counting and timing are performed on chip by a parallel counter and a NAND-tree network feeding sub-100 ps TDCs. The talk presents the rationale behind the choice of the LFoundry 110 nm CIS process and the status of the first prototype, with SPAD characterization, including irradiation and cryogenic tests, as an integral part of the activity. The challenges of a planar implementation and the collaboration and funding strategy are also discussed.

WS-02-13

PLATON - lessons learned on strategy and funding (#3420)

Davide Sgalaberna

ETH Zürich, Inst. f. Teilchen- und Astrophysik, Zürich, Switzerland

Abstract
The PLATON project aims to develop a 9x9 mm^2 SPAD array sensor (PLATON SPAD) for high-resolution particle tracking in scintillator-based neutrino detectors. PLATON SPAD is being developed for counting photons produced and transported by very thin scintillating fibers (0.5 mm diameter or lower) or as imaging sensor of plenoptic cameras that view unsegmented scintillator. PLATON SPAD requires single-photon capability. Sub-nanosecond timestamping allows to exploit the very fast response of the scintillator to reject random noise. Finally, the required ton-scale scintillator mass implies covering a few m^2 surface with PLATON SPAD sensors. In this talk, I will review the requirements of the high-resolution neutrino detectors under development within the PLATON project, focusing on both the advantages brought by SPAD arrays and the challenges that lead to the design choises. After elaborating possible funding strategies and mass production towards the realisation of the PLATON detectors and discussing about the lessons learned thus far, I will report on potential applications of SPAD array sensors beyond neutrino experiments, such as a novel monolithic PET scanner under design within the PLATON project, and the related technical challenges to overcome.

End-to-End SPAD Technology at Fraunhofer IMS (#3423)

Jennifer Ruskowski[1], Peter vom Stein[1], Martin Figge[1], Stephan Kolnsberg[1], Anton Grabmaier[1,2]

[1] Fraunhofer Institute for Microelectronic Circuits and Systems, Duisburg, Germany; [2] University Duisburg-Essen, Duisburg, Germany

Abstract
The development of the Fraunhofer IMS SPAD technology was originally driven by the requirements of large-scale SPAD arrays for LiDAR. Today, a 200 mm backside-illuminated SPAD process with wafer-to-wafer bonding is available, providing a versatile platform for highly integrated photon detection systems. The approach allows SPAD detectors and CMOS circuitry to be designed and optimized separately and subsequently combined, with the electronics positioned directly underneath the detector to maximize the photosensitive area and reach perfect timing symmetry.
Fraunhofer IMS covers the complete development chain, from SPAD and circuit design to semiconductor manufacturing and electro-optical waferlevel test, enabling sensor solutions tailored to specific detection challenges. The presentation will introduce this end-to-end approach, the rationale behind the technology, key

lessons learned during its development, and its potential for highly integrated digital SiPMs, including applications in particle physics.

WS-03 | Total-Body Kinetic Modeling Workshop

Summary

This workshop is designed to serve as a forum for discussing the emerging field of total-body PET kinetic modeling and its future directions. There are currently about 100 total-body PET and long axial field-of-view PET scanners operating across four continents. This workshop is timely to discuss the growing need for effective handling of total-body data for dynamic imaging and kinetic modeling. Such advancements are essential for extracting physiologically significant information that traditional static imaging methods could not achieve. We have invited experts with various levels of experience, including both senior and junior researchers, to present an overview of the technical challenges, progress, and clinical applications in this field. The workshop will facilitate not only rich exchanges of ideas but also offer a kinetic modeling an open-source software demonstrattion. Importantly, this workshop is designed to complement the existing MIC program on kinetic modeling, providing invited talks and practical sessions without overlapping with current offerings.

WS-04 | Emerging Directions in Theranostic Imaging: From PET and SPECT to Novel Modalities (onsite only)

Chairs:
Shiva Abbaszadeh (Santa Cruz)
Javier Caravaca (Berkeley)

sponsored by

Summary

Radiotheranostics, combining targeted molecular therapies with diagnostic imaging, holds great promise to transform healthcare decision-making by supporting individualized treatment planning, monitoring, and optimization. However, advanced imaging technologies for radiotheranostics are still emerging, and significant scientific, technical, and clinical challenges must be addressed to unlock their full potential in clinical environments. This workshop provides a dedicated forum for interested researchers to review past achievements, report recent progress and novel techniques, and discuss remaining challenges and future directions toward clinical translations. Key focus areas include optimizing the application of alpha and beta emitters enabled by novel imaging instrumentation, unconventional imaging techniques, advanced image reconstruction, dosimetry methods, simulation toolkits, and AI/ML methods for radiotheranostics.

We will invite interested presenters to submit separate abstracts to this workshop by August 31. We also invite industry partners and collaborators to attend and support this workshop.

We have created a special issue related to the content of this workshop in IEEE Transactions on Radiation and Plasma Medical Sciences (TRPMS). This Special Issue (https://ieee-trpms.org/current-special-issues/) will be a

collection of manuscripts associated with presentations and submitted abstracts in this workshop, after peer-review processes for the journal acceptance.

Abstract

Cancer treatment has shifted from empirical, toxicity-based dosing toward precision oncology guided by the specific genetic and molecular profiles of individual tumors. Within this framework, physicians, medical physicists, engineers, and scientists share the responsibility of developing tools to deliver high-precision treatments, predict therapeutic responses, and track disease progression. Radiotheranostics contributes to this approach by leveraging advanced radiochemistry to design highly selective molecules that deliver diagnostic or therapeutic radionuclides to target cells. Although routine at major medical centers for metastatic disease, broader adoption requires advances in imaging performance and targeted radiopharmaceuticals. Conventional PET and SPECT systems remain constrained by physical limits in spatial resolution, sensitivity, and quantitative accuracy, all of which are critical for clinical translation. Addressing these gaps requires higher sensitivity and spatial resolution, refined reconstruction algorithms for improved image clarity, precise image-based dose calculations, and system standardization. These needs drive hardware development toward total-body and organ-specific PET and SPECT systems, as well as new gamma, x-ray, and hybrid imaging methods. For high linear-energy transfer approaches like targeted alpha therapy, ex vivo micro-scale imaging is increasingly important to measure dose heterogeneity at the suborgan/cellular level. Concurrently, artificial intelligence is improving image reconstruction and dose prediction. Finally, key translational challenges must be addressed: ensuring trial reproducibility, integrating new methodologies into clinical workflows, and demonstrating cost-effectiveness alongside tangible patient benefit. This workshop brings together experts across these areas to collaborate and advance next-generation radiotheranostic technologies.

Abstract

The development of radiotheranostics would greatly benefit from quantitative imaging techniques that can simultaneously map the distributions of diagnostic and therapeutic radionuclides across spatial, temporal, and functional domains. To address this need, we will present the design of a proposed preclinical PET/SPECT platform consisting of a long-axial-FOV PET scanner with embedded CZT pinhole camera modules. The system is designed to simultaneously image both PET tracers and typical SPECT isotopes, as well as therapeutic radionuclides, such as Lu-177, Ac-225, Ra-223, and At-211.

The PET subsystem is based on dual-ended-readout BGO detectors with a diameter of 16 cm and an axial length of 16 cm. The BGO detectors in the central portion are purposefully positioned to leave small gaps to accommodate micro-gamma-camera elements (MGCE's) based on high-resolution CZT detectors with pinhole collimation for radionuclides. The MGCE's are designed to cover a wide dynamic range of 20 keV to 700 keV, so the combined PET and SPECT system will be capable of imaging virtually all commonly used SPECT isotopes and therapeutic radionuclides. In addition, data acquisition for the PET and SPECT subsystems is synchronized via a unified clock-and-trigger architecture. It enables coincidence detection of both PET and single-photon signals. Correlations among detected photons in the spectral and temporal domains are used to reject down-scattering noise in SPECT acquisition and to identify cascade emission of gamma rays from Lu-177 and Ac-225.

In this presentation, we will discuss a comprehensive design study of an integrated PET/SPECT imaging system and its potential to characterize the complex pharmacokinetics of radionuclide therapies.

Abstract

Molecular radiotherapy requires personalized dosimetry for efficient treatment and reduced toxicity, but current clinical imaging systems and miniaturized gamma-cameras lack the required capabilities. We developed a mobile gamma-camera with a 10×10 cm^2 field of view tailored for quantitative assessment of ^{131}I biokinetics during therapy of thyroid diseases. The system combines interchangeable 3D-printed tungsten collimators, a monolithic scintillator read out by a SiPM array, and commercial electronics. It achieves an intrinsic spatial resolution of 1.15 mm FWHM and negligible deadtime up to 150 kcps. Images are reconstructed in real time using an experimental data-trained convolutional neural network. The collimators and shielding were adjusted with Monte-Carlo simulations in order to reduce septal penetration and scattering. Preclinical studies demonstrated high quantitative accuracy, with activity bias below 5%, even for small sources. These performances stem from the camera's compactness and mobile design, which enables shorter detector-to-target distances, optimized viewing angles, as well as from its high overall spatial resolution (4–6 mm at 365 keV). Its mobility also avoids transporting radioactive patients, reducing radiation exposure for staff and other patients. A first clinical feasibility study involving 20 patients with benign thyroid diseases was completed in March 2025, to assess patient acceptance and image quality during planning and post-treatment follow-up, compared with a standard gamma camera (Syngula). Results indicate unprecedented image quality around 400 keV with direct quantitative information, particularly for post-therapeutic imaging, enabling improved assessment of heterogeneous ^{131}I distribution, including for Graves' disease. This highlights the potential of the camera for personalizing administered activity and, more importantly, estimating the dose actually absorbed during treatment, directly linked to therapeutic success.

This work was supported by NIH R01CA287205. We thank Robert Harrison for extensions to SimSET.

Abstract

We are developing a Personalized Remote Radiation Tracking Portable Organ Dosimetry Device (PRRT PODD) for at-home monitoring of patients receiving radiopharmaceutical therapy. The goal of this work is to provide a user and facility friendly device to enable organ at risk (OAR) dosimetry for patients undergoing Lu-177 DOTATATE treatment. The PRRT PODD consists of a portable frame with wings that encircle the patient's torso from the base of their kidneys to the top of their liver. In addition, there is a registration pad that enables precise positioning of the patient in the PODD for daily measurements. The patient lies down in a PODD template during their therapy qualifying PET/CT scan. This registers the PODD to their anatomy. Using software tools, a sensitivity matrix between the patient's OAR and tumors is determined for a two-dimensional (2D) array of potential detector locations along the surface of the PODD. Using this matrix, 16-32 detector locations are selected based upon the patient's specific anatomy to enable activity estimation for the patient's OAR. After a quantitative SPECT/CT scan acquired 24-hours after treatment, a PODD measurement will be made in clinic to normalize with the SPECT/CT scan. The PODD will then be sent home with the patient for fourteen 5-minute daily measurements. The PODD utilizes a carbon fiber base plate, a vacuumable Styrofoam registration pad, 3D printed wings, compact pinhole SiPM-based radiation detectors, battery-operated acquisition electronics, and a cell phone app that supports wireless transmission from the PODD's detector to a remote computer workstation. Our updated simulation software supports placement of a virtual 2D array of detectors on the polygonal surface defined by the PODD. An overview of the PODD development along with results from simulations based on human imaging examples will be provided at the workshop.

Abstract

In conventional ^{177}Lu imaging that relies solely on single photons or cascade gamma photons, the detection efficiency is fundamentally limited by the low photon emission probabilities. The decay of ^{177}Lu produces not only γ photons but also characteristic X-rays through the internal conversion process. In this work, we propose a multi-type time coincidence imaging strategy that exploits characteristic X-rays together with γ photons to improve the detection efficiency and image quality of ^{177}Lu imaging. The feasibility of X–X, X–γ, and γ–γ coincidence detection is analyzed based on the decay characteristics of ^{177}Lu, and a full-ring coincidence imaging system is subsequently employed for performance evaluation. Experimental results show that the integration of multiple coincidence-event types increases the system detection efficiency by 107.60\% and improves the contrast-to-noise ratio (CNR) by 8.39\% compared with conventional γ–γ coincidence imaging, while preserving nearly unchanged spatial resolution.

Abstract

Cascade gamma coincidence imaging is an alternative to conventional single photon imaging for therapeutic radionuclides such as ^{177}Lu by exploiting time-correlated cascade photon pairs. However, high spatial resolution and reliable quantitative accuracy remain challenging because of photon attenuation, scatter, partial volume effects. We developed a cascade-coincidence list-mode maximum-likelihood expectation-maximization (CCLM-MLEM) framework for a full-ring ^{177}Lu cascade gamma coincidence imaging system. Attenuation correction (AC) and scatter correction (SC) were incorporated into reconstruction, followed by absolute quantification and post-reconstruction partial volume correction (PVC). The system response matrix was modeled according to the cascade-photon detection geometry. The framework was evaluated using seven-point-source and hot-rod phantoms for spatial-resolution assessment, the modified image-quality phantom for quantitative evaluation, and the Mouse Whole-Body (MOBY) digital phantom for small-animal imaging. Direct backprojection (DBP) was used for comparison. CCLM-MLEM reduced the mean point-source FWHM from 2.20±0.10 mm with DBP to 1.51±0.27 mm and resolved 1.0-mm rods, compared with 1.5-mm rods using DBP. In the modified image-quality phantom, AC and SC improved activity and contrast recovery at comparable noise levels. In the MOBY phantom, the relative bias for a 4-mm tumor decreased from -57.19% without correction to 1.83% after AC, SC, and PVC. These results support high-resolution quantitative ^{177}Lu cascade gamma coincidence imaging and its potential for preclinical radiopharmaceutical imaging and dosimetry.

Abstract

Background: ^{225}Ac targeted alpha therapy requires quantitative post-therapy SPECT for verification and dosimetry. Multiple emissions, scatter, and inter-window crosstalk complicate reconstruction.

Methods: We developed a ^{177}Lu-informed deep support-driven kernel (DSDK). A support generator was pretrained on 63 clinical [^{177}Lu]Lu-DOTATATE SPECT scans using simulated projections at multiple count levels and a projection-consistency objective. For ^{225}Ac reconstruction, the learned support was used only to construct an image-domain kernel prior; activity remains governed by measured multi-energy projections and a Poisson model. Scatter and crosstalk are explicit projection-space physical models using MC-optimized DEW and self-consistent crosstalk correction for 218-keV, 440-keV, and joint-window reconstruction. Evaluation included MC calibration, single-sphere NEMA IQ scatter-window validation, dual-sphere IQ CNR-COV assessment at 15/30/60 s, and 10-patient [^{225}Ac]Ac-DOTATATE SPECT/CT evaluation. Baselines included OSEM, DDIP-TTA, and PET-guided methods; PET was not a DSDK input.

Results: MC selected a narrow 5% lower scatter window beside ±10% photopeak windows, with projection MSEs of 0.16/0.10 at 218/440 keV. Single-sphere joint-window CNR/SBR rose from 3.032/8.390 without scatter correction to 3.104/9.081. Dual-sphere DSDK with crosstalk improved the CNR-COV trade-off, especially at 15/30 s; at a representative joint window, CNR/COV was 22.2/0.87 versus 17.1/1.19 for DDIP-TTA. Clinically, joint-window DSDK achieved TBR 2.43 ± 1.27 and the highest lesion CNR among non-PET-prior methods. DSDK also achieved the highest joint-window lesion SSIM, 0.88 ± 0.05, without a PET-derived prior.

Conclusion: DSDK integrates support-level transfer, projection-consistent statistical reconstruction, and crosstalk physical modeling for quantitative multi-window ^{225}Ac SPECT and may support patient-specific dosimetry.

Abstract

Immediate visualization of therapeutic radionuclide distributions could provide useful spatial feedback during or shortly after interventional radionuclide therapy, but this use case requires a portable camera to acquire images quickly without close contact with the target region. We evaluated a Telephoto-Lens Magic-Cube portable gamma camera for rapid ^{177}Lu imaging using hybrid front-end long-hole geometric encoding and detector-side self-collimation encoding. A measured ^{177}Lu system matrix covered an 80 × 80 mm² field of view and source-to-camera distances of 8–22 cm. Across 54 point-source positions from 10–20 cm, mean absolute localization errors were 0.26, 0.32, and 2.58 mm along the x, y, and z axes, respectively. Representative dual-source reconstructions showed visually distinguishable hotspots separated by 5–7 mm at distances of 10–18 cm. At approximately 16 cm, all principal hotspots remained visible in 1 s reconstructions of three phantoms and an in vivo rat liver, with NCC values of 0.942–0.992 and transverse hotspot displacements of 0.27–1.12 mm relative to 300 s references. An excised rat liver containing 72.2 μCi of residual ^{177}Lu also showed a localized activity region. These results demonstrate the feasibility of rapid ^{177}Lu distribution imaging at extended working distances for procedure-room theranostic assessment.

Implementation of Radiation Detection Technologies, Quality Assurance, and Harmonized Control Standards for Theragnostic Programs in Emerging Healthcare Systems. (#3321)

Ian M. Rossi[1,2], María C. Plazas[1], Paul N. Martinez[1]

[1] Universidad Nacional de Colombia, Physics Department, Bogotá D.C., Colombia; [2] IEEE, Colombian Section, New York, USA

We gratefully acknowledge the support of the Universidad Nacional de Colombia and Vicerrectoría de Investigación through research project HERMES 64204, funded under the 2024 Innovation and Artistic Creation Projects Call.

Abstract

Theragnostic imaging is an emerging approach in precision oncology that combines molecular imaging with targeted radionuclide therapy. Its safe and effective implementation requires not only advanced radiopharmaceuticals, but also reliable radiation detection systems, standardized quality control (QC), and comprehensive quality assurance (QA) throughout the imaging and treatment workflow. This work focuses on the role of radiation detection technologies in theragnostics, including detector performance, calibration and verification of QC equipment, and radiopharmaceutical quality assessment.

Particular attention is given to radionuclide and radiochemical purity, activity calibrator verification, measurement traceability, and harmonized QA protocols. The work also addresses challenges in conventional gamma spectrometry, particularly spectral overlap in composite and low-activity samples, highlighting maximum-likelihood estimation (MLE) approaches for improved activity quantification of theragnostic radionuclides using NaI(Tl) detectors. In addition, emerging detector materials such as graphene quantum dots are considered for their potential to enhance radiation detection technologies.

The study discusses the challenges of implementing theragnostic programs in emerging healthcare systems, emphasizing the need for international standards, specialized training, appropriate infrastructure, and adaptable regulatory frameworks. These elements are essential to achieving accurate personalized dosimetry, reliable treatment planning, and safe, standardized theragnostic practices.

New Horizons in Ultra-High Resolution 3D CZT Detectors and its impact on preclinical SPECT/PET (#3309)

Alexander Cherlin[1], Freek Beekman[2,3,4]

[1] Kromek Ltd., Sedgefield, UK; [2] TU Delft, dept. Radiation Science & Technology, Delft, Netherlands; [3] Free Bee Int'l, Delft, Netherlands; [4] The Molecular Imaging Foundation, Delft, Netherlands

Abstract

Clinical and preclinical demand for higher-precision molecular imaging across an extended energy range is pushing gamma-ray detectors beyond the limits of conventional SPECT. CZT detectors offer excellent energy resolution and good sensitivity for high-energy isotopes, but position resolution and spectral distortions, including charge sharing and depth dependence, remain limited by pixel size, detector thickness, and cost of scaling readout electronics.

A novel approach is presented, using machine learning models trained on high-fidelity simulations to extract sub-pixel and depth-of-interaction (DOI) information from anode signals. Implemented in a prototype CZT gamma camera, the method achieves 10×10 sub-pixelisation of 2 mm pixels, DOI resolution of ~500-800 µm, and gamma-camera-level energy resolution with spatial precision approaching mid-range x-ray detectors, pointing toward a new class of high-resolution SPECT instrumentation.

A key challenge is the increased demand on readout speed and bandwidth. Accurate positioning requires acquisition of positive and negative signals across pixel clusters, increasing data volume and processing requirements while limiting real-time operation and scalability.

To address this, we explore neural network inference integrated directly into the detector front-end, enabling photon-by-photon signal processing. A dedicated ASIC will digitise and buffer electrode signals, which are then characterised by a neural-state machine that outputs high-level interaction data. A pulse-level simulation framework is being developed to train and validate front-end neural network models.We will present the first implementation of this framework on pixelated and drift-strip CZT detectors, with simulation results demonstrating improved multi-interaction event discrimination and reconstruction. This work provides a route to compact, high-resolution gamma detectors for next-generation theranostic imaging, from radionuclide therapy dosimetry to hybrid modalities. An example will be shown on what the impact of using high-end 3D CZT instead of traditional NaI Anger detectors could be on the architecture and performance of a new multi-isotope PET/PET PET/SPECT imaging module in Free Bee International's U-VET preclinical open PET/SPECT/CT/Optical/Ultrasound platform (World Molecular Imaging Society Innovation of the Year 2026)

A multimodal C-arm enabling concurrent X-ray and nuclear imaging for cost-effective theragnostic interventions (#3316)

Dennis R. Schaart[1], Martijn M.A. Dietze[2], Camiel E. Kerckhaert[2], Lukas Schröder[1], Marc Snoeyink[1], Niek Wijnen[2], Hugo W. De Jong[2]

[1] Delft University of Technology, Medical Physics & Technology, Delft, Netherlands; [2] University Medical Center Utrecht, Radiology and Nuclear Medicine, Utrecht, Netherlands

This work was funded in part by EU Horizon grant 101257367.

Abstract

Theragnostic interventions commonly require both fluoroscopic and nuclear image guidance. In liver tumor radioembolization, for example, ^{90}Y microspheres are injected into the liver bloodstream under fluoroscopy. First, ^{99m}Tc microspheres are administered, and a SPECT scan is made. Therapeutic ^{90}Y microsphere delivery is typically performed two weeks later, based on the results of the pre-treatment procedure. If a SPECT scan of the ^{99m}Tc microsphere distribution can be made inside the intervention room, the pre-treatment and treatment procedures can be merged into a single session, enabling in-situ adaptation of the catheter position and near-real time, personalized dosimetric treatment planning. Moreover, the burden for the patient as well as the overall cost of treatment are reduced. To this end, a first prototype of an interventional X-ray and scintigraphy imaging (IXSI) system was built at UMC Utrecht. It consists of a C-arm equipped with an X-ray tube and a detector stack consisting of an adapted X-ray flat panel detector positioned in front of a gamma camera fitted with a cone-beam collimator. Here, we report on two recent developments. First, a clinical trial is ongoing in which the first patients with liver cancer are receiving single-session radioembolization using the IXSI prototype. Second, X-ray imaging is currently limited to 70 kVp and the X-ray tube is translated off-focus from the focal point of the cone-beam collimator by 5 cm, to avoid blinding of the gamma camera by X-rays penetrating through the flat-panel detector. To enable concurrent, intrinsically co-registered X-ray and nuclear imaging using X-ray spectra up to 120 kVp, a novel detector stack is under development, comprising a gamma camera based on a low-afterglow, pixelated NaI(Tl) scintillator read out by SiPMs. An update of these developments will be presented at the workshop.

WS-04-12

Theranostic SPECT with High Energy Resolution CZT Detectors (#3334)

John R. Kuchta[1], Peter G. Hotvedt[1,2], Zhonghua Ouyang[1], David Paylan[1]

[1] MH3D Inc., Ann Arbor, USA; [2] University of Michigan, Nuclear Engineering and Radiological Sciences, Ann Arbor, USA

Abstract

An increasing number of isotopes have seen use in theranostic applications but have generally been limited by poor image quality or low quantification accuracy. These limitations are caused by factors like low emission intensities, clustered photopeaks, or lower system sensitivity. These factors drive the use of easier to image surrogate isotopes for biodistribution studies. Theranostic SPECT with CZT semiconductors reduces the need for traditional cut-and-count measurements and can produce quality reconstructions for isotopes that are otherwise difficult to image. The Alpha-SPECT^{TM} Mini preclinical device utilizes CZT semiconductors as the detecting medium, providing the highest energy resolution with a full-body field-of-view for mice. This SPECT imager has a 2.5% single-pixel energy resolution at 140 keV, and it has been used in the imaging of popular isotopes such as ^{225}Ac, ^{213}Bi, ^{212}Pb, ^{211}At, ^{177}Lu, ^{111}In, and ^{99m}Tc.

The detectors' superior energy resolution allows for discrimination of the clustered photopeaks in the X-ray energy regions of ^{225}Ac and ^{212}Pb. Projection windows with sufficient separation from the tungsten characteristic X-ray at 60 keV allow for removal of excess scatter in reconstructed images, one of the major image degradation factors in low-emission isotope imaging. The system's high sensitivity enables the dynamic imaging of fast decaying isotopes over the whole body of a mouse, such as ^{213}Bi with its 45-minute half-life. The dynamic imaging function has been utilized for binning as small as 2 seconds for ^{99m}Tc, 1 minute for ^{211}At, 15 minutes for ^{213}Bi, and 30 minutes for ^{225}Ac. This functionality unveils important information on theranostic isotope distribution shortly post-injection.

Fast Timing for High-Energy Gammas with GAGG and BGO for Improved Theranostic (#3313)

Fiammetta Pagano[1], Andrea Gonzalez-Montoro[1], Francis Loignon-Houle[1], Antonio Olmos Risen[1], Joshua W. Cates[2], Javier Caravaca[2], Antonio J. Gonzalez[1]

[1] Institute for Instrumentation in Molecular Imaging (I3M), CSIC-Universitat Politècnica de València, Valencia, Spain; [2] Lawrence Berkeley National Laboratory, Nuclear Science Division, Berkley, USA

This work was partially funded by the European Union (ERC, PHOENIX, 101164363). The authors express their gratitude to César Domingo-Pardo and his team for hosting the measurements in their laboratory.

Abstract
Time-of-flight (TOF) improves effective sensitivity and image signal-to-noise ratio in positron emission tomography (PET). Other medical applications that benefit from high time resolution include ion range verification in hadron therapy via prompt gamma imaging and dose verification in targeted alpha therapy via cascade gamma imaging. All these applications would benefit from intrinsically radiation-free scintillators, motivating the search for alternatives to LYSO. GAGG is a strong candidate due its high light yield, which enables good energy resolution, and to its fast decay time, which makes GAGG's time resolution very competitive. At high gamma energies — between 1–7 MeV, the range relevant to prompt gammas in hadron therapy and to characteristic gammas emitted in cascade by alpha-emitting isotopes — BGO also becomes particularly attractive, as its prompt Cherenkov photon yield increases significantly in this range.
Here, we present a proof-of-concept measurement of the time resolution of BGO and GAGG at ~1 MeV. Pairs of 3×3×15 mm³ BGO and GAGG crystals, coupled to FBK-NUV-MT SiPMs, were read out using state-of-the-art high-frequency electronics. Each crystal pair detected in coincidence the gamma cascade from a ^{60}Co source (1173 keV and 1333 keV gamma rays emitted with a sub-picosecond half-life). In our preliminary studies, we achieved a coincidence time resolution (CTR) FWHM of 120 ps for GAGG and 188 ps for BGO, while for 511 keV the CTRs are 179 ps and 245 ps, respectively. Additionally, simulations are used to investigate Cherenkov photon detection yield and time resolution as a function of gamma-ray energy. These results highlight the potential of GAGG and BGO both for TOF-PET and other emerging applications involving high-gamma energies.

Event-Based Alpha- and Beta- Particle Imaging with iQID: From Quantitative Digital Autoradiography to Isotope Identification (#3326)

Brian W. Miller[1,2], Jared W. Moore[2]

[1] The University of Arizona, Radiation Oncology and Radiology & Imaging Sciences, Tucson, USA; [2] QScint Imaging Solutions, Tucson, USA

Research reported in this publication was supported by the NIBIB of the NIH under SBIR Award Number R44EB035459.

Abstract
The growth of radiopharmaceutical therapy (RPT) has created an increasing need to characterize RPT distributions at microscopic spatial scales, where heterogeneity can strongly influence absorbed dose and biological response. This is particularly important for alpha-particle therapies, where information of the activity distributions is needed at spatial scales comparable to alpha-particle ranges in tissue (40–100 μm). The ionizing-radiation Quantum Imaging Detector (iQID) is a high-resolution imaging system developed for quantitative digital autoradiography of alpha- and beta-particle emitters at these spatial scales. iQID combines scintillation-based detection with CMOS-camera

imaging and real-time processing to localize individual particle interactions and record their spatial, temporal, and intensity information. Unlike phosphor imaging plate autoradiography, which integrates the cumulative signal from all radioactive decay events over an exposure, iQID detects and localizes individual scintillation events in real time. Event size, intensity, position, and time are retained as list-mode data, enabling high-resolution quantitative imaging of radioactive sources and radiolabeled tissue sections. Event characteristics can also distinguish alpha- and beta-particle interactions, allowing both emission types to be imaged simultaneously. The spatial and temporal information retained by iQID provides additional capabilities for characterizing radioactive sources. Changes in activity and decay behavior can be followed over time, and measured decay signatures can help distinguish radionuclides within mixed sources. This presentation will describe the iQID imaging approach and highlight applications in quantitative alpha/beta autoradiography, source characterization, isotope identification, radiopharmaceutical biodistribution, and micro-scale dosimetry.

How the next generation digital autoradiography can provide insight into theranostic bioequivalence (#3315)

Stephen Adler

Frederick National Laboratory For Cancer Research, Clinical Research Directorate, Bethesda, USA

Funded by the NCI Contract No. 75N91019D00024.

Abstract

Introduction: Theranostic cancer treatments rely on ligands which can be tagged with two different isotopes. One for imaging and one for treatment. The imaging ligand is used as a proxy for monitoring the ligand used to treat the target tissue. Key to using the imaging agent to measure the dosimetry of the treatment ligand is knowing the bio-equivalence of the ligand pair. Bio-equivalence is defined as equal biological interaction of two ligands within tissue. This can be achieved with the Quantitative Particle Identification Autoradiograph (QPID).

Materials and Methods: The next generation of spectral autoradiograph has been developed which mates a Timepix3 sensor developed by the CERN Medipix collaboration with a CeBr3 scintillation crystal. This allows one to use the gamma emission energy in forming autoradiograph images of tissue samples harvested in bio-distribution studies. The QPID time resolution is on the order of 1.6 ns allowing for the detection of single decays, thus achieving alpha and beta identification through ionization topology and energy deposition in the Timepix3 sensor, and spectral gamma emissions from the imaged sample.

Results: The QPID can segregate alpha and positron emissions, generating separate quantitative alpha and positron autoradiograph images from a sample which contains both an alpha and positron emitting ligand. This provides a mechanism to analyze co-injected theranostic imaging and treatment ligands. Using these separate images, one can measure the uptake and distribution in the same tissue sample. Furthermore, one can directly measure the pharmacokinetic properties of both ligands and measure their bio-equivalence.

Conclusion: Measuring any bio-equivalent deviation of the two ligands can be used to adjust the imaging agent activity and pharmacokinetic properties to more accurately be used as a proxy to measure the treatment effects and dosimetry results of the treatment ligand.

This work was supported by NIH UH3EB034686.

Abstract

PET and SPECT are often used even when radionuclides emit complementary radiations. Gamma-positron imaging exploits nuclides that emit a prompt gamma with a positron: annihilation photons define a PET line of response and prompt-gamma Compton interactions define a cone. Their intersection can estimate the radionuclide decay location more directly than PET alone.

We are developing a brain-dedicated gamma-positron imager using crossed-strip CZT detectors, event-correlated radiation transport, and GPU-accelerated list-mode reconstruction. The system records PET coincidences, prompt-gamma Compton events, and triple events in which both signatures arise from one decay. We evaluated event-class-specific LM-MLEM, conventional joint-Poisson reconstruction, and an event-type-conditioned method designed to preserve the localization value of triple events.

UAMonteCarlo preserves the lineage of prompt photons, positrons, annihilation photons, and secondaries from emission through detector interaction, allowing detector response, event classification, sensitivity, and reconstruction to be evaluated in one framework. In simulated 44Sc studies, all event classes localized point sources correctly. In a hot-rod phantom, rod-to-background contrast was 1.36 for PET-only, 1.14 for prompt-only, 4.93 for triple-only, 3.24 for conventional combined, and 3.86 for event-type-conditioned combined reconstruction, showing that triple events are uncommon but spatially informative.

The project also applies complete radiation-transport histories to emerging theranostic imaging. For 149Tb, gamma-positron events from the positron branch could image the same radiopharmaceutical responsible for alpha therapy. We are also applying the framework to 203Pb surrogate imaging for 212Pb-targeted alpha therapy. Together, these studies show how preserving decay and particle histories can inform detector design, reconstruction, quantitative imaging, and dosimetry.

Abstract

Multiplexed PET (mPET) enables simultaneous imaging of multiple radiotracers in a single acquisition by exploiting radionuclide-specific signatures beyond conventional 511-keV annihilation photons. Positron–prompt gamma emitters such as ^{124}I, ^{86}Y, or ^{44}Sc can generate triple coincidences that help distinguish them from pure positron emitters. This opens new opportunities for theranostic imaging, where complementary tracers could simultaneously characterize therapeutic targets and tumor biology, investigate intra- and inter-lesion heterogeneity, assess radiopharmaceutical biodistribution and dosimetry, or monitor early biological response to treatment.

We present a modular mPET framework applicable to different radionuclides and scanners. It incorporates all the corrections and reconstructions required for quantitative PET while adapting to different scanner capabilities. When available, we exploit energy and time-of-flight information, while coincidence multiplicity alone provides radionuclide-specific information in more limited systems. The method also includes radionuclide-specific positron-range correction for each separated image.

We quantitatively evaluated the approach with combinations such as ^{18}F+^{124}I, ^{18}F+^{52}Mn, ^{68}Ga+^{86}Y, and ^{89}Zr+^{86}Y across several preclinical and clinical PET scanners. Studies ranging from simultaneous tracer imaging in mice to multi-radionuclide phantom experiments demonstrated recovery of the individual radionuclide distributions across systems with different detector characteristics.

These results demonstrate the translation of mPET across PET scanners and radionuclide combinations. mPET could extend PET from a predominantly single-tracer technique toward a multidimensional molecular imaging platform in which complementary aspects of patient selection, treatment delivery, and response are interrogated within the same imaging session.

Abstract

Pixel detectors for X-ray science typically require pixel pitches of less than 1 mm and operation at photon fluxes greater than 10^9 ph s^{-1} mm^2. For lead halide perovskite detectors to be viable in these applications, they must demonstrate good spatial uniformity, as well as operational stability over a period of hours or days. Here, we present results of synchrotron experiments in which the detection performance of melt-grown $CsPbBr_3$ devices, solution-grown $FAPbBr_3$ devices and CZT were each measured at 20 keV X-ray fluxes up to 10^9 ph/s/mm^2, demonstrating the linear response of the material to changing X-ray fluxes. Microbeam maps of device response to single-photon fluxes of 50 keV X-rays were used to quantify spatial variations in the charge collection efficiency and rise time of events.

Abstract
Scintillator-based photon counting detectors (PCDs) couple a fast scintillator with a silicon photomultiplier (SiPM) and associated readout electronics. The characteristics of the scintillator and SiPM that are required for competitive performance are not yet clear, and it is sometimes felt that bright scintillators and high photodetection efficiency are needed. We use numerical modeling to study this question, using a cascaded system model with multiple stages to quantify the effects of light yield, SiPM sensitivity, and energy binning. Effects such as SiPM saturation, Swank noise, and K-escape are also included as optional stages. We find that using relatively dim components (5x dimmer than that assumed in previous modeling studies) introduces little harm into spectral imaging tasks, but the penalty of K-escape is large. Future prototype detectors should emphasize K-escape, stopping power, and speed rather than light yield or photodetection efficiency.

JS-01-03

A four side buttable system in package for medical and industrial Photon-Counting CT (#1574)

Torsten Solf[1], Thomas Froehlich[2], Enrique Hostalet[3], Riad Kanan[2]

[1] AMS Osram, Garching, Germany, Germany; [2] AMS Osram, Jona, Switzerland; [3] AMS Osram, Valencia, Spain

Abstract
We present the second generation of a four-side buttable module solution (AS592xM) for spectral CT detectors with a pixel matrix of 72x24 covering an area of 24.5 mm x 8.57 mm with a pitch of 365 µm x 340 µm. In combination with a suitable direct detection material like CdTe or CZT it detects individual X-ray photons with five programmable thresholds. Improvements have been made to reduce power consumption down to 0.35mW/pixel while maintaining low noise performance (380 e rms). Count rate stability is based on two different methods: a static leakage compensation (SLC) as well as a base line restorer circuit (BLR). The new SLC in combination with an auto-zero scheme in the frontend suppresses the effect of potential 1/f and Random Telegraph Noise (RTN) noise from the amplifiers. The adjustable BLR compensates for static and dynamic baseline shifts up to 700nA of leakage current per pixel. Measurements with and without CZT will be shown to quantify the energy resolution and count rate stability over input flux for different operation modes to quantify S/N for the different energy bins. Additionally, the MTF is characterized to project spatial resolution on system level.

This work was supported by NIH under Grant No. 1R01CA297470.

Abstract

In this presentation, we will report the design and imaging performance of our third-generation Alpha-SPECT-mini system (the Alpha-SPECT-mini-ZM, where ZM stands for Zoom-in Microscope), which combines ultra-narrow micro-ring collimators and a vibrational aperture-scanning scheme to provide ultrahigh spatial resolution for *in vivo* 3-D autoradiography of α-RPT in small lab animals. The system uses a cylindrical ring of 10 detector panels, each comprising 2×6 HEXITEC/CZT detector modules. Each CZT module has a 2×2 cm^2 active area with 80×80 pixel array at 250 μm pitch and offers 1.5 keV FWHM energy resolution at 122 keV. The Alpha-SPECT-mini-ZM system uses a two-section collimator ring that combines pinhole apertures for whole-body imaging and ultra-narrow micro-ring apertures for zoomed-in ultrahigh-resolution imaging of a focal area with a 5-mm-diameter FOV, switched via a motorized stage. To offer an ultrahigh imaging resolution that overcomes the limited detector pixel size, the system employs a vibrational scanning strategy with MUCRB-guided acquisition optimization. Preliminary simulations with micro-hot-rod phantoms show the micro-ring collimator achieving better than 160 μm resolution at practical sensitivity. Further phantom studies will be carried out to characterize the performance of the system.

This study was funded by the Commercialization Promotion Agency for R&D Outcomes (COMPA), supported by Korea's Ministry of Science and ICT (MSIT, grant No. 2710086067), and by the Advanced GPU Utilization Support Program (No. 02-26-01-0492) of MSIT. The MCNP 6.3.0 Theory & User Manual is openly available as a technical report cleared for public release.

Abstract
Although large language models (LLMs) perform well on general-purpose programming tasks, their accuracy drops sharply when applied to domain-specific simulation codes such as Monte Carlo N-Particle (MCNP). Within the nuclear sector, security policies and export-control rules typically forbid uploading inputs to cloud-hosted LLM services, so review tools must instead run on-premise atop openly released models. This study introduces a coordinated multi-agent framework that automatically inspects and repairs MCNP input decks. Three role-specific agents—a Supervisor, a Fixer, and a Validator—drive the workflow, supported by 16 auxiliary tools and an optional retrieval-augmented generation (RAG) module that consults the MCNP user manual. To measure performance, we assembled a 360-case benchmark covering six representative nuclear-engineering scenarios. Our pipeline reaches a 75.8% success rate, exceeding a single-agent reference by 15.5 percentage points and confirming that role-based orchestration is an effective strategy for trustworthy MCNP code repair in fully local deployments.

A Compact Educational Platform for Demonstrating TDAQ Concepts in Particle Detector Systems (#1734)

Raffaele Giordano[1,2], Mihai Cuciuc[3,4]

[1] University of Naples "Federico II", Naples, Italy; [2] INFN, Naples, Italy, Naples, Italy; [3] Extreme Light Infrastructure - Nuclear Physics, IFIN-HH, Magurele, Romania; [4] Pomelo Instrumentation SRL, Bucarest, Romania

The authors are sincerely grateful to Dr. Fulvio Coppola[1] from CESMA for ensuring the safety of radioactive materials. Work funded by CSN5 of INFN (MEMPHYS experiment).

Abstract

Particle physics experiments rely on complex detectors, where trigger and data acquisition (TDAQ) systems play a key role. These systems are typically expensive, large-scale, and accessible only in specialized laboratories, limiting students' early exposure to the fundamentals of TDAQ. To address this gap, we developed a compact, low-cost educational platform that reproduces the main elements of a particle-detector readout chain in a form suitable for university laboratories. The platform is based on an Arduino UNO R4 Wi-Fi, a custom piggy-back board, and a detector module consisting of a CsI(Tl) scintillator coupled to a silicon photomultiplier. The system integrates bias-voltage generation and temperature monitoring, programmable pulse amplitude discrimination, peak detection, digitization, and USB or Wi-Fi data transfer to a personal computer.

The platform enables students to explore the main TDAQ concepts, including trigger formation, latency, dead time, buffering, and threshold setting. By progressively implementing different firmware strategies, from simple trigger polling to interrupt-driven and hardware-assisted acquisition, students gain direct insight into the relation between system design and detector performance. Educational activities on slow control, such as bias-voltage calibration, detector monitoring, and gain stabilization, are also possible. After firmware development, students can perform gamma-spectroscopy measurements using low-activity radioactive materials. Examples include potassium chloride salt substitutes, where the 1460.8 keV photopeak from ^{40}K can be observed, and thoriated tungsten welding electrodes, which exhibit several gamma lines from thorium decay products. In this contribution, we discuss the platform, the TDAQ topics addressed, and student experiments that demonstrate its educational potential.

Abstract

Photon-counting computed tomography (PCCT) requires scintillators with ultrafast decay times, ultralow afterglow, and high light yields (LY) to prevent pulse pile-up and image ghosting under continuous high-flux X-rays. While cerium-doped lutetium yttrium oxyorthosilicate (LYSO:Ce) is a benchmark material, its intrinsic ~40 ns decay time and deep-trap-induced afterglow constrain its PCCT applications. This work demonstrates systematic defect and crystal-field engineering to modify LYSO:Ce crystals, establishing a highly customizable material platform.Four distinct codoping strategies are evaluated to overcome the speed-efficiency-afterglow trade-offs. First, multi-site co-doping was employed to convert Ce^{3+} in ultrafast LYSO (LYSO-U) scintillation crystals into fast-emitting Ce^{4+}, introducing a non-radiative path within the crystal. This breaks the intrinsic lifetime barrier, achieving a 7.3 ns decay component and suppressing afterglow to 0.02% at 40 ms, while preserving an LY of 25,000 photons/MeV. Second, multivalent Al/Mn codoping utilizes bidirectional energy transfer to deliver a 9.6 ns decay, 446 ppm afterglow at 40 ms, and an LY of 31,300 photons/MeV. Third, isovalent Ge substitution (LYSGO:Ce) increases local crystal-field

splitting to thermodynamically deepen emitting states for enhanced carrier capture, elevating the LY to 38,700 photons/MeV and supporting a 25.6 lp/mm spatial resolution. Finally, trace Co^{2+} doping (~330 ppm) passivates oxygen-vacancy traps without severe lattice distortion, boosting the LY to 37,800 photons/MeV. By elucidating these physical mechanisms, these tailored, charge-sharing-free scintillator platforms address the diverse architectural demands of advanced PCCT detectors.

Abstract

Scintillation based photon counting detectors (PCDs) attracts great interest because of its fast time response, crystal separation to suppress the charge sharing and wider choices of sophisticated scintillation crytals. We have designed and fabricated a custom fine-pitch (250 μ m) 10 × 10 Ce:YAGG- SiPM array whose size is comparable to the current commercial compound semiconductor based PCD. The performance was characterized in terms of energy resolution, spatial resolution, count rate capability and imaging capability. The measured results shows 28% @ 122 keV moderate energy resolution, 2.9 LP/mm spatial resolution comparable to the existing CT, 20 Mcps/mm2 at 20 % loss count rate capability. The comparison between YAGG and GFAG shows the significant supression of K-α escape cross-talk in the energy spectrum. The investigation with other scintillation crystals, such as LYSO will be shown. The different concentration of Optiray contrast agent (Iodine) with 10 m-50 mg/mL was clearly identified with 4 thresholds photon counting system.

Abstract

In this work, the latest developments in glass-less Through-Silicon Via (TSV) integration of FBK NUV-HD-MT Silicon Photomultipliers (SiPMs), targeting next-generation Time-of-Flight Positron Emission Tomography (ToF-PET) detectors in the framework of the PetVision project, are presented. The NUV-HD-MT technology platform provides an outstanding baseline for TSV integration, featuring Photon Detection Efficiency (PDE) exceeding 65% at $420\ \text{nm}$, optical crosstalk below 5% at $15\ \text{V}$ excess bias, and a Single-Photon Time Resolution (SPTR) as low as $\simeq 18\ \text{ps}$ FWHM for a single SPAD. The glass-less TSV architecture eliminates any permanent intermediate layer at the scintillator interface by removing the temporary glass carrier after backside thinning to $150\ \mu\text{m}$, enabling optimal optical coupling and preserving the fast-timing performance of the underlying technology. The TSV development follows a structured, learning-cycle-based R\&D approach. Preliminary characterization of the Learning Cycle 1 (LC1) front-side production confirms that timing performance remains at state-of-the-art levels, with a Coincidence Time Resolution (CTR) of $\simeq 75\ \text{ps}$ FWHM achieved using a $3\times3\ \text{mm}^2$ SiPM coupled to a $2.8\times2.8\times3\ \text{mm}^3$ L(Y)SO:Ce:Ca scintillator, and an SPTR of $\simeq 25\ \text{ps}$ FWHM obtained for a single $50\ \mu\text{m}$ SPAD. Back-side processing of the LC1 wafers has been completed and full electrical and functional characterization is now underway. The Learning Cycle 2 (LC2) design, featuring an optimized 4×2 SiPM array with a $3\ \text{mm}$ channel pitch for direct crystal matrix coupling and a reduced TSV count of one per channel for improved yield, represents a significant step toward a robust, production-ready solution.

Abstract

In time-of-flight PET, coincidence time resolution (CTR) is essential, with the ultimate aim of reaching 10 ps CTR [1]. Cherenkov radiation in BGO crystals, offers a path toward this target, but its low photon yield demands detectors combining high photon detection efficiency, low dark count rate, and fast single-photon time resolution (SPTR) [2].

In DIGILOG, we segment state-of-the-art analog SiPMs into smaller clusters called μSiPMs [3]. With fewer SPADs per cell, μSiPMs have lower capacitive loading, enabling simpler, faster electronic interfaces and higher-resolution timestamping via time-to-digital converters (TDCs) in proximity through 3D stacking. Optical and system-level simulations identify a granularity of 6×6 SPADs per μSiPM (100 μSiPMs in 3×3 mm²) as optimal for Cherenkov-based BGO timing [4].

The μSiPM top tier, fabricated by FBK in NUV-HD-MT technology [5], uses Single-Cell TSVs for independent microcell cathode access without fill-factor loss. We present two 110 nm CMOS readout architectures, both based on a current-mirror front-end, a Vernier ring-oscillator TDC [6], and a serial interface. Two ring oscillators run at slightly different frequencies setting the LSB; the sequences are compared as in a Vernier line until pulses align, and T is computed from the counts n1 and n2. The first implementation, an 8×8 TDC array with 20 ps target LSB, has been fabricated; a Vernier LSB of 19 ps and 4.4 ps RMS jitter have been measured [7]. The second upscales to a 9×9 array with three TDCs per μSiPM on independent threshold levels of a multi-level comparator, enabling MD-SiPM-like operation [8] and order-statistics-based timing [9]. It targets a 6 ps LSB at 2.0 mW per channel, with an on-chip PLL (<5 ps FWHM jitter) stabilizing the oscillators against PVT. Post-layout simulations yield SPTR <20 ps (FWHM) and INL ±1.1 LSB. Die-to-die 3D bonding of the two tiers is ongoing at T-Micro.

Real-Time DOI Layer Prediction in TOF-PET Detectors via FPGA Neural Network (#2254)

Shuiting Xin, Zhenjie Han, Xiang Zhang, Xinyu Lv, Shaoping Chu

united imaging, MI, Shanghai, China

Abstract

Depth-of-interaction (DOI) information is critical for improving time-of-flight (TOF) precision in positron emission tomography (PET) detectors. Traditional DOI estimation methods, such as dual-ended readout and layered crystal arrays, require complex fabrication or additional photodetector channels, increasing system cost and degrading timing performance. This paper presents a machine learning framework for real-time DOI layer prediction in single-ended readout LYSO crystal arrays (5×6 structure coupled to a 2×2 SiPM array). A neural network takes normalized SiPM energy ratios and crystal position as inputs and outputs DOI classification into 2, 3, or 6 depth layers. A symmetry-based training strategy is introduced to enhance model generalization across crystal positions, effectively quadrupling the training data through rotational coordinate transformations. Experiments with a collimated ^{22}Na source demonstrate classification accuracy of 40–80% across six depth layers. Validation using top radiation data confirms the model's generalization from lateral irradiation (training) to normal incidence (clinical deployment). DOI-corrected coincidence time resolution (CTR) evaluated on 4320 crystals shows improvements of 2.25 ps (2-layer), 3.41 ps (3-layer), and 5.18 ps (6-layer). The two-layer neural network has been implemented on FPGA with fixed-point arithmetic, achieving a processing rate for real-time inference. Ongoing work focuses on system-level integration and image quality evaluation.

Physics-Informed Deep Learning on FPGA for Inter-Crystal Scattering Correction in ToF-CT (#1776)

Lamyae Jdid, Réjean Fontaine, Audrey C. Therrien

Université de Sherbrooke, Interdisciplinary Institute for Technological Innovation, Sherbrooke, Canada

This research was funded in part by the STRATEGIA Initiative of the FRQNT, Project 355619. Audrey Corbeil Therrien holds the Canada Research Chair in Real-time embedded intelligence for ultra high rate detectors. This research was enabled in part by support provided by Calcul Québec and the Digital Research Alliance of Canada.

Abstract

Time-of-Flight Computed Tomography (ToF-CT) enhances contrast-to-noise ratio by suppressing patient-scattered photons. However, the fine pixel pitch required for sub-millimeter spatial resolution intensifies inter-crystal scattering (ICS), a confounder that conventional energy-based discrimination cannot resolve under polychromatic X-ray sources, ultimately compromising spatial resolution. To overcome this limitation, we introduce the first real-time, physics-informed ICS correction framework deployed at the FPGA-based detector readout of ToF-CT systems. Built on Physics-Informed Knowledge Distillation (PI-KD), the framework compresses a high-capacity teacher (AUPRC = 0.99) into a compact student architecture suitable for embedded deployment. Specifically, the distillation objective constrains the student to remain consistent with Klein–Nishina scattering kinematics and Monte Carlo-derived interaction priors, thereby preserving the physical structure of its spatiotemporal and energetic representations under aggressive compression. Quantization-Aware Training (QAT) further enables hardware-native INT8 inference, reducing the parameter footprint to ~2.3 kB with negligible performance loss. Post-synthesis on a Xilinx ZCU104 at a 200 MHz target clock confirms real-time operation beyond the 1 MHz acquisition target, sustaining 1.32 MHz per inference instance with 0.83 µs latency, while INT8 LUT-based arithmetic leaves all DSP blocks free (28% LUT, 38% BRAM, 0% DSP).

Cherenkov Photon Counting, Labeling, and Multi-Photon Timing Estimation for sub-100 ps CTR BGO TOF-PET Detectors (#2761)

Joshua W. Cates, Seungeun Lee, Ryan Heller, Woon-Seng Choong

Lawrence Berkeley National Laboratory, Applied Nuclear Physics, Berkeley, USA

Abstract

We have developed a bismuth germanate (BGO) Cherenkov and Scintillation photon counting time-of-flight positron emission tomography (TOF-PET) detector which can count and provide unique timestamps for detected optical photons. This allows 511 keV photon time of interaction estimators to be derived from the prompt Cherenkov light without influence from scintillation light, which has a much higher variance from time of detection. This detector concept is also capable of three-dimensional positioning of 511 keV photon interactions, allowing for position and depth-of-interaction dependent optical transit time skew corrections to be applied to the prompt estimators. Information from this detector concept can be used to classify each detected optical photon as Cherenkov or scintillation. In this work, we show how labeling each detected photon as Cherenkov/scintillation and only incorporating prompt information into a timing estimator that averages timestamps for events with more than one detected Cherenkov photon significantly improves both achievable coincidence time resolution with BGO and also the TOF kernel shape by significantly reducing the long tails from time pickoff on scintillation light. We constructed a 16x16x15 mm^3 BGO photon counting detector prototype and evaluated its performance in coincidence with a fast reference detector. Incorporating the information from multiple labeled Cherenkov photons improved CTR from 159 ps to 137 ps FWHM, and the long scintillation tail was reduced to a small fraction of the total coincidence distribution. When considering all events with at least one Cherenkov photon detected, CTR was 122 ps FWHM with a Gaussian kernel shape. CTR improved to ≤100 ps for events containing 2 or more detected Cherenkov photons. We present these methods, along with a new detector concept with high Cherenkov photon detection efficiency to enable ≤100 ps CTR in a BGO TOF-PET detectors that also have high 511 keV photon detection efficiency.

3D-cylindrical microdetector arrays for microdosimetryin proton therapy (#2475)

Carla Riera-Llobet[1], Celeste Fleta[1], Paula Ibáñez[2], Iván López[1], **Consuelo Guardiola**[1]

[1] National Center of Microelectronics (IMB-CNM, CSIC), Radiation Detectors Group, Barcelona, Spain; [2] Univ. Complutense de Madrid (UCM), Nuclear Physics Group, Madrid, Spain

The project has received support from the Spanish government through the ‘María de Maeztu Unit of Excellence’ accreditation (CEX2023-001397-M / AEI/10.13039/501100011033)

Abstract

Proton therapy provides high dose conformity, improving protection of organs at risk, especially for radioresistant tumours, sensitive locations, and paediatric cases. However, reported toxicities may be linked to high linear energy transfer (LET) effects. To address this issue, IMB-CNM has developed a new radiation detector architecture [1]: 3D-cylindrical silicon microdetectors, with micrometre-scale sensitivity to quantify LET. Starting from this kernel, different configurations have been designed and fabricated to cover a wide range of resolutions and radiation sensitive areas from a 11 × 11 array (2 mm × 2 mm) [2] to a linear array of 200 of those microdetectors covering 0.4 mm × 12 cm [3, 4], among others. To the best of our knowledge, these are the largest radiation sensitive surfaces covered with microdosimeters so far. Each of these multi–arrays are integrated in customized electronics readouts by using multichannel ASICs to DAQ. The ASIC enables the beam trigger and an analogue output for 128 microdetectors. Additionally, special pitch–adapters have been manufactured for each configuration to connect the signal channels with the ASIC readouts properly.

In this work we present the first measurements in proton therapy centres under clinical fluence rates (10^8 p/cm2s) across different regions of the beam. Additionally, Geant4-based Monte Carlo simulations were performed to crosscheck the experimental results. Representative microdosimetry energy spectra were obtained for some clinical depths as well as the comparison with the patient simulated LET values obtained by a treatment planning software.

The results show the feasibility of quantifying distributions of microdosimetry lineal energy values under clinical conditions, which are compared with clinically simulated for the first time.

Role of Al_2O_3passivation on high-resolution 4H-SiC radiation detectors

(#1671)

Krishna C. Mandal[1], Sandeep K. Chaudhuri[1], Frank H. Ruddy[2]

[1] University of South Carolina, Electrical Engineering Department, Columbia, USA; [2] Ruddy Consulting, Nuclear Detection and Imaging, Mount Pleasant, USA

Abstract

Oxide passivation plays a critical role in stabilizing semiconductor radiation detectors by suppressing surface states and enabling low-leakage, high-resolution operation. In this work, Al_2O_3-passivated Ni/4H-SiC Schottky radiation detectors were fabricated on n-type epitaxial layers of varying thickness (20, 150, and 250 μm) using pulsed laser deposition without post-deposition annealing. All devices exhibit uniform rectification with Schottky barrier heights of ~1.3 eV, low interface trap density (~10^9 $cm^{-2}eV^{-1}$), and reverse leakage dominated by Poole-Frenkel transport. Capacitance-voltage measurements indicate a flat-band potential of ~2.3 V due to fixed oxide charge, while frequency dispersion confirms minimal contribution from slow interface states. Under 5.486 MeV α-particle irradiation, the detectors demonstrate efficient self-biased operation with energy resolution of 3.3% at 0 V, improving to ~0.5-0.6% at -40 V. A detailed comparison of two nominally identical 150 μm detectors reveals significant variation in charge collection efficiency (~0.99 vs ~0.6) and energy resolution despite similar electrical characteristics, indicating that bulk carrier trapping dominates performance variability. Deep-level transient spectroscopy identifies $Z_{1/2}$ centers as the primary recombination-active defects limiting resolution across all thicknesses. A broad high-energy feature is definitively resolved, for the first time in Al_2O_3-passivated 4H-SiC Schottky detectors, using isothermal transient spectroscopy into two distinct defect levels at E_C-1.05 eV and E_C-1.1 eV, attributed to oxide-related ON2a/b states. This work establishes a unified understanding of interface and bulk defect effects in SiC radiation detectors for optimizing high-resolution operation in harsh environments.

Vacuum-deposited metal halide perovskite film as a radiation scintillator (#2471)

Muzzamer Zahid[1], Amy J. Dickinson[1], Jayana Jayarathne[1], Carol Crean[2], Paul Sellin[1]

[1] University of Surrey, School of Mathematics and Physics, Guildford, UK; [2] University of Surrey, School of Mathematics and Physics, Guildford, UK

Abstract

Metal halide perovskite (MHP) has been widely investigated as a radiation scintillator. Current solution-processing methods used to fabricate the MHP film suffer from toxic solvent issues and are limited in their ability to scale up for a large area detector. Single-source vapour deposition offers a solvent-free alternative that uses a single precursor, making it a promising technique for scalable film fabrication. In this study, $(BA)_2PbBr_4$ films were fabricated using SSVD onto glass substrates under high vacuum. The films were subsequently characterised, and the X-ray scintillation performance was evaluated. The results revealed that SSVD produces a thick film with a mean thickness of 10.5 ± 4.0 um and has a polycrystalline grain distribution. Energy-dispersive X-ray spectroscopy confirmed that the SSVD method preserved the composition, as the Br/Pb ratio is consistent with the theoretical value 4 for $(BA)_2PbBr_4$. Photoluminescence spectroscopy revealed a narrow peak emission 423 nm with FWHM 13 nm in close agreement with reported values for solution-grown crystals, confirming that the optoelectronic structure is preserved after deposition. Under 50 kVp X-ray irradiation, the film exhibited a fast, stable, linear dose rate response yielding scintillation sensitivity of 2464 μC Gy^{-1} cm^{-2}. These results demonstrate that SSVD is a viable, solvent-free method for fabricating MHP scintillator films with direct implications for scalable fabrication for next-generation medical imaging detectors.

This work was supported by the Slovak Research and Development Agency by grant No. APVV-22-0382 and the grant of the Scientific Grant Agency of the Ministry of Education of the Slovak Republic and the Slovak Academy of Sciences No. 2/0084/20, and Funded by the EU Next Generation EU through the Recovery and Resilience Plan for Slovakia under the project No. 09I05-03-V02-00073.

Abstract
Diamond is a highly promising semiconductor material for ionizing radiation detection. Diamond-based detectors are excellent candidates for neutron detection due to interactions on relatively light carbon nuclei. Moreover, these detectors exhibit low sensitivity to X-ray and gamma radiation that often accompany neutron flux. Neutrons with energies below approximately 6 MeV are detected solely via elastic scattering on carbon nuclei within the diamond crystal. At higher energies, nuclear reactions occur, producing alpha particles, protons, and ions that can be detected by the detector. In this experiment, we use a single-crystal CVD diamond detector to detect fast neutrons with energies ranging from 300 keV to 18.5 MeV. A diamond detector has square contact dimensions of 3.6 × 3.6 mm^2 and a thickness of 0.5 mm. Testing the detector with an alpha-particle source showed a high-energy resolution of about 0.4% at 5.5 MeV. The detector was used to detect monoenergetic neutrons ranging from 250 keV to 911 keV, 3.5 MeV to 4.5 MeV, and 14.6 MeV to 18.5 MeV, generated by p-T, D-D, and D-T nuclear reactions at Van de Graaff accelerator, respectively. The single-crystal diamond detector showed good linearity and excellent detection properties. In the detected spectra, all main neutron-detector interactions were identified.

Improving the spectral resolution of photons in silicon Timepix3 by correcting for the cluster size and by lowering the Krummenacher current (#1416)

Jindrich Jelinek[1,2], Benedikt Bergmann[1]

[1] Czech Technical University, Institute of Experimental and Applied Physics, Prague, Czech Republic; [2] University of Geneva, Department of Particle and Nuclear Physics, Geneva, Switzerland

B. Bergmann acknowledges support from the Czech Science Foundation under Registration Number GM23-04869M.

The authors would like to thank Petr Smolyanskiy (IEAP CTU) for his help with the measurements, Jan Zemlicka (IEAP CTU) for lending a piece of gadolinium metal, and Tomas Slavicek (IEAP CTU) and Bartolomej Biskup (IEAP CTU) for their assistance with the radioactive sources.

Abstract
We investigated ways to improve the spectral resolution of a Timepix3 hybrid pixel detector with a 1 mm thick silicon sensor for X-ray and soft gamma photons. A standard procedure is to calibrate the time-over-threshold (ToT) to deposited energy for each pixel, but even then, there remains room for improvement. The first

improvement was lowering the Krummenacher current (Ikrum) to increase the ToT at even low-energy deposits to get a finer resolution. The second novel improvement was creating an additional calibration on cluster energies, taking into account the cluster size. It was observed that clusters of larger size feature a higher energy than smaller clusters created by the same photon source. The cluster energy could therefore be corrected based on its size, and we found that this correction is linear for each cluster size. Both the lowering of the Ikrum together with the cluster size correction decreased the full width at half maximum (FWHM) by 17-35 % compared to the initial settings in the energy range of 4-136 keV. The higher the photon energy, the larger the percentage decrease in FWHM. We intend to utilize the enhanced spectral resolution in Compton X-ray polarimetry. There, the coincident events of a Compton scattering followed by a photoabsorption are measured. The sum of the deposited energies in the two events gives the original energy of the photon. The FWHM of coincident pairs of clusters decreased by 22-44 % compared to the initial settings in the energy range of 43-136 keV.

Abstract

Accurate interaction position reconstruction in radiation detectors is often limited by the lack of tractable likelihood functions and the stochastic nature of particle transport and charge induction processes. In this work, we present a simulation-based inference framework for 3D Cadmium Zinc Telluride drift strip detectors (3D CZT DSD) that learns a probabilistic inverse mapping from Charge Induction Efficiency signals to interaction positions using Monte Carlo generated training data. We formulate the reconstruction problem as Neural Posterior Estimation and train a neural network to predict a Gaussian approximation of the posterior distribution over interaction positions. The model is optimized using negative log-likelihood, enabling simultaneous estimation of interaction positions and associated uncertainties in a single amortized inference step. Preliminary results on synthetic datasets show that the proposed method produces meaningful uncertainty estimates that provide insights into detector response variability compared to deterministic regression approaches.

Abstract

The cadmium zinc TElluride Radiation Imager (TERI) was successfully launched to the International Space Station (ISS) on April 21, 2025 as a part of the Department of Defense's Space Test Program (STP-H10) mission. The primary mission of TERI is to space-qualify large-volume 4×4×1.5 cm^3 pixelated CdZnTe (CZT) detectors. The system is composed of four of these advanced detectors, each of which is 3D position sensitive, allowing for Compton event imaging. Here, we report on the one-year in-orbit performance results of TERI, including measurements of the background rate, which align with expected orbital variations. We analyze the 511 keV line and observe no significant degradation over nine months in orbit. Additionally, we observe multiple spectral lines, several of which are consistent with known activation lines.

The Shape of Light (#3451)

Sara Cazzoli

Instituto de Astrofísica de Andalucía, Astrophysics, Granada, Spain

Abstract

The term Big Bang evokes a deafening sound. Yet in the Universe, it is not sound but light that serves, so far, as the most powerful messenger of information. Our eyes were the first instruments through which humanity began to understand the nature of our Universe. Today, telescopes are our eyes to the cosmos, and they are coupled with a wide variety of instruments capable of collecting, manipulating, and transforming the light that we can ultimately study in order to unravel the secrets of the Universe. Thanks to them, we obtain information as distant and ancient as the Cosmic Microwave Background and as close and young as the whims of our own star, the Sun. What stories do the different forms of light tell us? Whether through “simple” photon counts, spectra, or even the absence of light, its many forms reveal different information about our Universe. Light is also a fundamental element in the arts. In the performing arts, it is crucial for creating emotions—often becoming a narrative language—in photography, it builds atmospheres, from the depth of black and white to the intensity of the most vivid colors; and in architecture, it defines spaces and highlights textures. Light is an essential element both in the artistic experience and in our understanding of the Universe. The Shape of Light is, more than a talk, a journey through light across astronomy, physics, and art.

Facile, scalable and high-yield synthesis of zero-dimensional copper halide $Cs_3Cu_2Cl_5$ scintillator with near-unity quantum yield for high-resolution X-ray imaging applications (#1659)

Young Seung Choi[1], Jaeyoung Im[2], Kang Heo[3], Sung Oh Cho[2], Bo Kyung Cha[4], **Byungha Shin**[1]

[1] KAIST, Materials Science and Engineering, Daejeon, South Korea; [2] KAIST, Nuclear and Quantum Engineering, Daejeon, South Korea; [3] Viewworks, Anyang, South Korea; [4] KERI, Ansan, South Korea

Abstract

Metal halide perovskites, particularly copper halide variants, have emerged as promising scintillators owing to their large Stokes shift, high photoluminescence quantum yield (PLQY), and efficient radioluminescence. Here, we demonstrate a dioxolane-mediated reaction synthesis as a simple, scalable, and high-yield strategy for producing $Cs_3Cu_2Cl_5$ powders with near-complete conversion. By employing low-polarity yet water-miscible dioxolane as the reaction medium together with an aqueous H_3PO_2 additive, the solubility imbalance between the precursors inherent to low-polarity solvents is effectively addressed. This approach enables stoichiometry-controlled dissolution–precipitation under a low-polarity reaction environment and the formation of phase-pure $Cs_3Cu_2Cl_5$ powders with near-unity PLQY. The powders show bright green emission at ~530 nm and retain over 80% of their initial efficiency after 300 days of ambient storage without encapsulation, demonstrating remarkable intrinsic stability. $Cs_3Cu_2Cl_5$-based composite films deliver an ultrahigh light yield of ~98,000 photons MeV^{-1}, greatly surpassing that of commercial scintillators such as Gd_2O_2S and CsI:Tl, and exhibiting excellent dose linearity and long-term irradiation stability. When integrated into commercial flat-panel detectors, the $Cs_3Cu_2Cl_5$-based composite films successfully enabled high-quality 2D radiographic and 3D computed tomography imaging, directly verifying their compatibility with existing X-ray detection systems. This facile and efficient synthesis, together with the demonstrated device-level imaging performance, highlights $Cs_3Cu_2Cl_5$ as a scalable and practical candidate for next-generation X-ray scintillators.

Abstract

Halide perovskites are promising scintillator materials for radiation detection and medical imaging because of their excellent optical and scintillation properties. Since the surface quality of single-crystal scintillators strongly affects light extraction and detector performance, polishing is an essential step in scintillator fabrication. However, conventional wet polishing processes are not suitable for water-sensitive crystals such as $Cs_3Cu_2I_5$ (CCI). In this work, hydrophobic solvents were investigated as polishing media for water-sensitive CCI single crystals. Three hydrophobic solvents—squalane, silicone oil, and mineral oil— were used as dispersion media for 1 μm alumina abrasives, followed by toluene rinsing after polishing. Among them, squalane showed the best polishing performance, yielding the lowest surface roughness (R_q=17.29 nm), the highest transmittance of 78.21%, and the narrowest rocking-curve FWHM of 0.025°. In addition, sequential polishing in squalane using P2000 sandpaper, P4000 sandpaper, and 1 μm alumina enhanced the light yield and improved the energy resolution from 6.53% to 5.83%. These results identify squalane as a promising polishing medium for water-sensitive halide perovskite scintillators.

Organic Scintillator Light Yield Models for Sub-MeV Neutrons in EJ301D and d-stilbene (#1369)

Christian A. Irvine[1,2], Tyler C. Borgwardt[1], Robert A. Weldon Jr.[1], John Mattingly[2]

[1] Los Alamos National Laboratory, NEN-2, Los Alamos, USA; [2] North Carolina State University, Nuclear Engineering, Raleigh, USA

This work was supported by the US Department of Energy through the Los Alamos National Laboratory. Los Alamos National Laboratory is operated by Triad National Security, LLC, for the National Nuclear Security Administration of U.S. Department of Energy (Contract No. 89233218CNA000001).

Abstract

Six commonly used models for neutron induced light yield in organic scintillators were fit and analyzed using measurements of a 2.54 cm diameter by 2.54 cm long right circular cylinder of EJ301D and a (5.08 cm)3 custom made cube of deuterated trans-stilbene-d12 (d-stilbene). Measured neutron energies spanned 300 keV to 2200 keV for the EJ301D scintillator and 200 keV to 2500 keV in d-stilbene. The model fits and experimental analysis methods were verified by examining the agreement between the predicted light output spectrum and the measured light output spectrum for several simulated quasi-monoenergetic neutron sources. Birks model inaccurately predicted highly quenched light yield for sub-MeV neutrons in both scintillators. The addition of a second order quenching term to the Birks model by Chou significantly improved the models accuracy, however its behavior is non-physical if extrapolated beyond the measured neutron energies. The model derived by Voltz accurately fit the measurement of both scintillators for all measured neutron energies. Further investigation into the ability to extrapolate based on these semi-empiric models would be valuable given the non-physical behavior of well-fitting models.

Application of neutron sensitising layers to plastic scintillator (#2414)

Jack R. Hitchens, Chris Allwork, Shivani L. Chauhan, Tom Crane, Tom Heather, Matt P. Taggart

AWE Nuclear Security Technologies, Reading, UK

Abstract

Eljen plastic scintillator disks have been coated with layers of neutron sensitiser in a systematic study on the thickness of neutron detection layers. Here we discuss the impact of enhancing standard plastic scintillator (PVT) with coatings containing both lithium and boron isotopes. The application of these layers enhances the material to provide a mechanism for detecting neutron radiation. A systematic study was performed to assess the impact of sensitiser thickness on neutron detection efficiency and neutron-gamma pulse shape discrimination (PSD) performance. Samples were exposed to the mixed radiation fields of a ^{252}Cf source, and a sample of plutonium. The results demonstrate clear neutron-gamma discrimination in sensitised samples, with measured figures of merit in excess of 3 recorded for optimised lithium-rich coatings. This is comparable performance to established dual-mode detectors. These findings show that thin, externally applied neutron-sensitising layers provide an effective route to enhancing the performance of conventional plastic scintillators. This approach may offer a low-cost means of upgrading existing detector systems in nuclear security applications.

Abstract

Cerium-doped gadolinium gallium aluminium garnet (GAGG:Ce) is a novel scintillator with excellent scintillation properties. It is suitable for use in various basic science research and applications. Because the scintillation light is quenched for charged particle detection, it is necessary to use beams from accelerators to calibrate the energy response. Measurements of energetic charged particles incident on three GAGG:Ce crystals were performed using accelerated protons, ^{4}He, and ^{12}C at 0°C and 20°C in consideration for detecting charged particles in the earth's radiation belts for space weather modeling and for deploying in dosimetry devices in ion therapy, respectively. The Birks factor which quantitatively describes the extent of quenching was deduced from the experimental data. For all three GAGG:Ce scintillators, the Birks factor decreases with the atomic number Z of the incident ions. Furthermore, less light quenching, a smaller Birks factor, was observed for GAGG:Ce at 0°C. The quenching for the Mg-codoped GAGG:Ce which has a shorter decay time constant, was found to be less temperature dependent compared to the other two GAGG:Ce crystals.

Temperature Dependence of Pulse Shape Discrimination in SiPM-Based EJ-276D Detectors (#1585)

Jacob W. Fritchie, Angela Di Fulvio, Gabriella Gariazzo, Grant Roche, John Leland

University of Illinois Urbana-Champaign, Nuclear, Plasma, and Radiological Engineering, Urbana, USA

This work is funded in-part by Sandia National Laboratories (SNL) LDRD Award 2308289. SNL is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration (NNSA) under contract DE-NA0003525. This research was performed under appointment to the Nuclear Nonproliferation International Safeguards Fellowship Program sponsored by the U.S. NNSA's Office of International Nuclear Safeguards.

Abstract

The temperature dependence of pulse shape discrimination performance was investigated for three commercial silicon photomultiplier technologies coupled to an EJ-276D organic scintillator. Measurements were conducted at 22 °C, 30 °C, 40 °C, and 50 °C using PuBe sources. Pulse shape discrimination was quantified using the tail-to-total ratio and figure of merit. For all devices, the figure of merit increased at 30 °C. The Broadcom device exhibited the highest performance, increasing from 1.12 at 22 °C to a maximum of 1.17 at 30 °C before decreasing to 0.76 at 50 °C. The Onsemi and Hamamatsu devices showed smaller improvements, with figure of merit values increasing from 0.86 to 0.89 and 0.84 to 0.90, respectively, between 22 °C and 30 °C. At 50 °C, all devices exhibited reduced performance due to increased silicon photomultiplier thermal noise. Temperature-dependent changes in pulse shape were observed, with increasing temperature producing faster decay and modifying the balance of prompt and delayed scintillation light, improving neutron-gamma separation at intermediate temperatures. Despite degradation at higher temperature, all devices maintained effective discrimination up to 50 °C. These results demonstrate that silicon photomultiplier-based detectors are capable of robust neutron-gamma discrimination at elevated temperatures relevant to safeguards applications.

Abstract

The HIE-ISOLDE Timing Array for Reaction Studies (HISTARS) project at CERN is developing a specialized detector system designed to measure the lifetimes of excited nuclear states. For efficient particle detection, thin square GaGG(Ce) are utilized alongside YSO due to their high density and fast scintillation properties. This work evaluates the performance of GAGG(Ce) crystals coupled with two distinct photosensors: a Hamamatsu R9779 photomultiplier tube (PMT) and an array of four silicon photomultipliers (SiPM) using a custom-designed circuit. These configurations were tested in combination with a $LaBr_3$(Ce) detector to facilitate coincidence measurements. Data acquisition was performed using high-speed digitizer to extract timing and energy information. This article reports on the comparative performance of both readout methods, specifically characterizing pulse shape discrimination capabilities, energy resolution, and the coincidence time resolution for alpha-gamma events. Although the energy resolution is acceptable and it has a good pulse shape discrimination capability, the measured timing limitations show that the current configuration is not ideal for the HISTARS array. These results will guide the selection of better-suited materials for high-precision timing at HIE-ISOLDE.

Abstract

Time-of-flight positron emission tomography (ToF-PET) has boosted PET image quality significantly in the last years. During its first inception it was built with cross-luminescent BaF_2 crystals, which have since been replaced by LYSO. Recently, cross-luminescence has regained popularity with new scintillators being developed. However, BaF_2 and the recently developed Cs_2ZnCl_4 could not improve on the LYSO state-of-the-art coincidence time resolution (CTR) (56 ps for 2x2x3 mm³ and 95 ps for 3x3x19 mm³). As Cs_2ZnCl_4 shows a significant Cherenkov production, we combined it with the DIGILOG approach to boost its timing performance. The DIGILOG approach segments the sensor into µSiPMs and has shown an improved timing performance for BGO due to its Cherenkov radiation and an improved SPTR. Here, we simulated a 3x3x3 mm³ and a 3x3x20 mm³ Cs_2ZnCl_4 crystal coupled to seven different µSiPM arrays. The simulation included noise factors like dark counts, cross-talk, SPAD dead time and analog noise. It was designed with a PDE of 60 % and an SPTR of 25 ps. This resulted in an improved CTR of 34+/-4 ps for an array of 20x20 µSiPMs coupled to a 3x3x3 mm³ Cs_2ZnCl_4 crystal compared to the non-segmented SiPM at 48+/-3 ps. Furthermore, for the 3x3x20 mm³ crystal, a CTR of 64+/-4 ps was reached with a 10x10 µSiPM array, while the non-segmented SiPM showed a CTR of 84+/-3 ps. The results of the segmented SiPMs improve on the LYSO state-of-the-art. Additionally, they demonstrate that the DIGILOG SiPM approach improves timing performance not just for BGO, but also for other scintillators with high Cherenkov yield, ultra-fast emission and low light yield. We also provide motivation to optimize sensors for Cs_2ZnCl_4, which could enable better timing performance than the LYSO state-of-the-art.

Fast or Adapt: Proportional Gas in γ-ray Fields (#1278)

Jakub Prchlik, Eric Yokie, Arlo Petitjean, David O'Connor

Reuter-Stokes, LLC, Twinsburg, USA

Abstract

Background γ-ray fields complicate neutron measurements for Nondestructive Assay (NDA) of Nuclear Materials and the next generation of advanced reactor designs, including non-light water (non-LWR) and Small Modular Reactors (SMRs). Neutron sensitive proportional counter design for high γ-ray fields often focus on optimizing ion collection time and integrating low-Z materials. In these counters, the metal cathode produces most of the Compton scattered electrons, which deposit unwanted energy and signal in the gas. The long path length for Compton electrons in the counter gas means the counter gas pressures may be optimized to increase the ratio of ion-to-electron energy deposition. Here we present gas mixture and pressure optimization for ion-to-electron energy deposition using SRIM simulations. The simulation output is then tested experimentally for its effect on neutron sensitivity in γ-ray fields between 1 R/Hr and 100 R/Hr. The ion-to-electron energy deposition ratio shows promise as an additional design consideration for neutron sensitive proportional counters in γ-ray fields, even though the experimentally measured optimum pressure of 0.5 atm for He/N_2 95/5 is lower than the simulated optimum pressure. Future experiments with a current sensitive preamplifier (CAEN A1427) will improve neutron counting for 1 to 100 R/Hr γ-ray fields.

Abstract

Monolithic silicon CMOS Sensors represent a considerable step forward in charged particle and photon sensing, and emerge as a promising embodiment for the design of novel deep-silicon photon-counting X-ray Computed Tomography scanners . This work presents the first characterization of the ARCADIA MD3 Fully-Depleted CMOS sensors, which technology is currently the baseline for the development of innovative sensors under the framework of the EIC Pathfinder Open 1MICRON project. We report on the characterisation results using an edge-on geometry and a focused synchrotron X-ray beam at the DESY test facility. The x-rays impinge on the edge of the sensor, increasing the active sensor depth seen by the photons, which consequently improves the quantum efficiency with respect to a face-on configuration. A 37 keV focused beam incident parallel to the sensor surface allowed scans along the two directions of the sensor edge, enabling the extraction of the active sensor thickness and mechanical tilt via pixel intensity profiles. Lateral scans across pixel boundaries revealed a periodicity of the spatial modulation of mean cluster size compatible with the pixel pitch of the matrix. Taking the cluster size as the main figure of merit, the performance of the sensor was evaluated at different thresholds and multiple bias voltages in order to assess the variation in the Coulomb cone and collection dynamic. The measurements are supported by Allpix Squared Monte Carlo framework, demonstrating good consistency between the simulated and the real domain.

Abstract

High-energy physics experiments currently use Low Gain Avalanche Diodes (LGADs) as part of their time-of-flight layers to track particles, thanks to their unique temporal resolution and radiation hardness. With increasing deposited charge, the gain was observed to decrease. This gain suppression effect originates from the electrostatic field screening produced by the avalanche multiplication charge. This work investigates the resilience of the LGADs to the gain suppression by characterizing a set of detectors with different gain layer designs and thicknesses, using Transient Current Techniques.

Abstract

Mobility (μ), lifetime (τ), and mobility–lifetime product (μτ) are key metrics for semiconductor radiation detectors. Highly concentrated trapping centers or defects can distort the internal electric-field distribution, producing reduced-amplitude slow-rising charge-sensitive preamplifier pulses that degrade carrier-transit and charge-collection analyses. Although slow-rising-pulse rejection is commonly used to sharpen pulse-amplitude peaks and suppress low-amplitude tails, this work extends its use to charge-carrier transport characterization. A CdZnTeSe detector [1, 2] was characterized at room temperature under electron- and hole-transit-dominant conditions using ^{241}Am alpha irradiation. Pulse-shape analysis rejected slow-rising pulses for key metrics extraction. In electron-transit-dominant measurements, the fast-rising pulse events preserved the bias-dependent peak-centroid trend and yielded $(\mu\tau)_e$ = 5.7 × 10^{-4} cm²/V, μ_e = 576 cm²/V·s, and τ_e = 1.0 μs, consistent with reported values [3,4]. For hole-transit-dominant measurements, all-pulse events obscured the pulse-amplitude peak and hindered Hecht fitting. After rejection, we obtained $(\mu\tau)_h$ = 2.1 × 10^{-4} cm²/V, τ_h = 0.7 μs, comparable to reported values [5], with μ_h = 318 cm²/V·s. Using the rise-time peak as the representative transit time, both all-pulse and fast-rising-pulse events yielded similar μh values. However, when the median rise time of all-pulse events was used instead, drift velocity did not show a clear linear dependence on electric field, whereas fast-rising-pulse events retained linearity. This reflects the need for careful consideration of slow-rising components and the transit-time definition. These results show that slow-rising-pulse rejection enables reliable transport characterization beyond spectral improvement.

Abstract

This paper presents a methodology for measuring the trajectories of high-energy electrons through materials utilizing a transmission electron microscope (TEM). This novel technique is implemented to diagnose and quantify the mechanism for enhanced radiation attenuation via nanostructures. Rather than an imaging technique, the TEM is applied to radiation shielding measurements as an adaptable electron source with functionality for various beam energies, amperage, alignments, and exposure times alongside an array of precise electron detectors. By utilizing energy filtering and direct electron detection capabilities, scattering profiles are measured with minimal background contributions. This TEM method is leveraged to describe particle transport in nanostructures. Palladium nanoparticles at various monodisperse sizes are synthesized via heat injection and deposited into an epoxy matrix. The palladium epoxy nanocomposites are sectioned with an ultramicrotome to thicknesses of 70 to 1000 nm containing nanoparticle sizes of 5 to 50 nm at 20% of the total weight fraction. Scattering profile measurements at various beam energies are conducted with a variety of sample thicknesses, nanoparticle sizes, and composite fractions. Scattering profile measurements also include bulk, homogeneous palladium samples in contrast to nanomaterials composed of identical atomic percentages. Simulation of the experimental scattering profiles demonstrate an understanding for the phenomena behind nanostructured attenuation enhancement, bolstering advanced nuclear technology via a foundational description for particle transport in nanostructures.

Abstract

New generation of vertex detectors must have excellent thermo-mechanical stability, and all-silicon ladders are considered as promising solutions for future detectors. However, power consumption asymmetries between the active area and periphery can induce large temperature gradients, and in some cases a combination of air and liquid cooling will be required to achieve homogeneous thermal profiles. Microchannel cooling offers a competitive alternative to traditional cooling systems. The short thermal path between the heat load and sink gives an increased thermal evacuation performance, combined with the reduced material needed for the integrated microchannels and the reduced Coefficient of Thermal Expansion mismatch between the cooling and sensor materials to obtain an optimized cooling for radiation detectors. The development of the technology needed for the integration of the sensor with the microchannels in a single piece is an ambitious challenge, as the conditions for the microchannel formation must be compatible with the sensor, requiring the optimization of the fabrication to ensure the compatibility with CMOS processes. As a demonstrator, all-silicon ladder prototypes with integrated cooling microchannels are presented. Power consumptions for the active area and periphery of the ladders are emulated using integrated aluminum heaters. The bulk in the active area is thinned from 600 to 50 microns, and the design of the microchannels cooling circuit, integrated in the periphery of the ladder, is optimized using finite-element simulation packages. Variations of prototype ladders with different sizes, microchannel dimensions, and integrated using different wafer bonding techniques are fabricated and evaluated in detail in this work.

Abstract

This work presents a novel neutron detector concept aiming to provide detection efficiency and background levels equivalent to conventional ^{3}He-based detectors, whilst boosting the maximum counting rate by several orders of magnitude. The detector retains the form-factor of a standard ^{3}He tube and uses the same working gas mixture of ^{3}He with admixture of CF_4 as the stopping gas. The key innovation is a fast optical readout of CF_4 prompt scintillation light using silicon photomultiplier (SiPM) sensors. The target performance is a detection efficiency equivalent to that of a standard ^{3}He tube under identical gas filling conditions, gamma sensitivity below 10^{-6}, and a maximum counting rate of 2 MHz/pixel, orders of magnitude improvement over existing detectors. The fast emission of CF_4 scintillation light is the enabling factor for achieving ultra-high counting rates. CF_4 exhibits a considerable photon yield, with one scintillation band in the UV and another in the visible region of the spectrum, with several thousands of photons emitted per neutron event. The efficient collection of light by the SiPMs constitutes a critical design parameter, addressed in this study through Monte Carlo optimization. The gas mixture composition is optimised to maximise the scintillation yield, and a gas purification system can be integrated into the detector to ensure long-term stability. The first experimental results of a detector prototype characterisation on a neutron beamline at the Institut Laue-Langevin (ILL) will be presented.

Characterization of 3D ultra-thin silicon-based thermal neutron detectors (#3088)

Felipe Zamorano, Iván Lopez, Martín Pérez, Javier Bravo, Celeste Fleta, Consuelo Guardiola

Institute of Microelectronics of Barcelona, Barcelona, Spain

This project has received funding from the Consejo de Seguridad Nuclear (CSN) under the project Subvenciones 2022 SUB-08.

Abstract

Neutron contamination in advanced radiotherapy and other mixed radiation environments has become an increasing concern due to the limitations of conventional neutron detectors under intense gamma background conditions. In this work, ultra-thin 3D silicon neutron detectors specifically designed for operation in mixed radiation fields were experimentally characterized under thermal and high-energy irradiation conditions. The detectors, consisting of 20 µm-thick silicon sensors paired with ^{6}LiF neutron conversion layers, were tested at the FANT thermal neutron facility and at the CERN High-Energy Reference Field (CERF). Measurements included reproducibility, angular dependence, bias voltage operation, and discrimination threshold effects using a low-voltage FPGA-based readout system. The results showed stable operation under mixed radiation fields, moderate angular dependence, and strong dependence of the response on detector bias and discrimination threshold. The ultra-thin detector architecture enabled high gamma rejection capability, enabling reliable neutron detection under intense photon background conditions. These results demonstrate the suitability of 3D ultra-thin silicon detectors for compact real-time neutron monitoring in radiation protection and medical applications.

Abstract

Scintillator-on-fiber (SOF) detectors utilizing Liglass scintillators show strong potential for neutron flux monitoring in intense radiation environments due to their high radiation hardness and fast response. Previous studies have typically employed fragmented scintillators in SOF detectors due to the difficulty of μm-scale machining. In this work, Li-glass scintillators with well-defined dimensions (1×1×0.5 to 0.25×0.25×0.5 mm^3) were precisely fabricated using laser cutting, enabling a systematic investigation of the effect of scintillator size on neutron response linearity in an acceleratordriven neutron beam. With pulse-shape discrimination (PSD), the results show that neutron signals measured with scintillator sizes larger than 0.5×0.5×0.5 mm^3 become blurred in the P_{SP}-channel scatter plot due to gamma-ray contributions and pulse pile-up at an accelerator current of 250 μA. In contrast, the smallest scintillator (0.25×0.25×0.5 mm^3) maintains clear separation between neutron and gamma-ray signals. Analysis of the maximum shift error σ_m of the neutron peak centroid further indicates that this smallest scintillator effectively suppresses pileup, achieving $\sigma_m = 0$. In terms of linearity, scintillators with sizes below 0.75×0.75×0.5 mm^3 yield coefficients of determination $R^2 > 0.99$ when processed using a two-dimensional fiducial cut, satisfying the requirements for neutron flux monitoring in boron neutron capture therapy (BNCT). These results demonstrate the feasibility of optimizing Li-glass scintillator size and volume in SOF detectors to achieve reliable neutron flux monitoring in BNCT applications.

This work was supported by JSPS KAKENHI Grant Number 26K03212. The authors thank the members of the Radiotracer Imaging Project, QST, for their valuable support during the experiment.

Abstract

The Coded Cube Camera for Gamma-ray (C3G) is a 4π gamma-ray imager designed to estimate gamma-ray source distributions from direction-dependent detector response patterns. In this study, we developed a 24-detector C3G consisting of 24 HR-GAGG scintillators and applied it to a plant radioisotope (RI) imaging experiment using $^{11}CO_2$ gas. In the plant RI imaging experiment, approximately 300 MBq of $^{11}CO_2$ gas was supplied to a plant placed in an experimental chamber to image the transport of ^{11}C-labeled photosynthates within the plant. During this experiment, the C3G was placed outside the chamber, and the dynamics of $^{11}CO_2$ gas were continuously measured with an acquisition time of 1 s per measurement. As a result, the inflow of the gas into the chamber was clearly visualized. In addition, the reconstructed image intensity decreased exponentially over time. The half-life estimated from this intensity change was 20.70 min, which was in good agreement with the known half-life of ^{11}C, 20.34 min. These results demonstrate that the 24-detector C3G can visualize dynamic gaseous radioactive sources and estimate temporal changes in radioactivity from reconstructed image intensity. This capability is expected to be useful for applications such as radioactive gas leakage monitoring, environmental monitoring, and nuclear security.

Method for determining lithium ore's grade based on photoneutrons' lifetime measurement (#1637)

Minfeng Yu[1,2], Yigang Yang[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Tsinghua University, Key Laboratory of Particle & Radiation Imaging, Beijing, China

This research was supported by the Natural Science Foundation of Beijing, China (Grant No. L252023).

Abstract

Analysis of lithium ore grade is industrially significant for efficient lithium resource development and utilization, enabling improved production efficiency and reduced costs. Lithium has a large neutron absorption cross-section, and changes in lithium grade can affect the neutron lifetime, which is inversely proportional to the macroscopic absorption cross-section of ore. In this paper, a method for determining lithium grade through neutron lifetime measurements based on an e-LINAC driven photoneutron source is applied to the online analysis of lithium ore grade. Since lithium does not emit gamma rays upon neutron absorption, the neutron lifetime is measured from the time distribution of capture gamma rays induced by neutrons in the matrix elements of the medium. The feasibility of this approach has been demonstrated in experiments using various lithium nitrate solutions as simplified media. Meanwhile, the effect of neutron diffusion was investigated by simulations. The potential of neutron-induced prompt gamma analysis for reducing interference caused by variations in matrix composition is discussed. Further simulation studies and system design are in progress.

Abstract

Silicon photomultiplier (SiPM) based thermal neutron detectors have been developed at Oak Ridge National Laboratory for single crystal diffraction instruments. They have potential as good replacements for current 3He detectors on neutron reflectometers due to their high spatial resolution and fast scintillator decay time. The current software-implemented position fitting on these detectors is limited due to the processing required for the recursive least-squares algorithm. In this work, we present a fast method for determining neutron position that can be run on the Field-Programmable Gate Array (FPGA) chip that is already installed on the detector. This method compares the collected event data with pre-determined shapes stored on FPGA memory in parallel, and determines the one with the least linear error. Using this method for neutron positioning takes less time than the hardware defined dead time. Count-rate and spatial resolution results collected at the High-Flux Isotope Reactor are presented, with output count rates > 500 kcps achieved, an order of magnitude greater than the software fitting method.

Localization of uranium samples in large cemented nuclear waste using active photon interrogation and a Bayesian inversion (#1492)

Malo Lebreton[1], **Malo Lebreton**[1], Benoit Geslot[1], Benoit Geslot[1], Cédric Carasco[1], Cédric Carasco[1], Bertrand Pérot[1], Bertrand Pérot[1], Claire Michelet[2], Claire Michelet[2]

[1] Commissariat à l'énergie atomique et aux énergies alternatives, CEA/DES/IRESNE, St Paul Lez Durance, France; [2] Université de Bordeaux, CNRS-IN2P3/LP2IB, Bordeaux, France

Abstract

CEA Cadarache currently manages over 6,000 historical 870 L nuclear waste packages. To ensure long-term safety, French regulatory authorities require a precise characterization of each unit, specifically regarding structural integrity, fissile material mass and total activity of alpha emitters. However, the high density and volume of 870 L concrete waste packages result in significant signal attenuation, making standard passive gamma spectrometry or passive and active neutron measurements inefficient to assess the mass of nuclear materials. To maximize the signal-to-noise ratio, a specific Active Photon Interrogation (API) approach is developed inside the CINPHONIE irradiation bunker of CHICADE facility, at CEA IRESNE, Cadarache, France. This method makes use of inorganic BGO scintillators to measure high-energy delayed gamma rays from short-lived photofission products induced with a high-energy bremsstrahlung photon source, i.e., a 18 MeV LINAC. A Bayesian framework is applied to infer both the mass and the position of nuclear materials from angular acquisitions. This article is focused on testing API

framework in the case where the source of the signal is located in a homogeneous environment. Based on the promising results presented here, future developments will focus on the heterogenous case.

Hybrid Temperature Compensation and Radiation Damage Recovery with Scintillation Detectors (#2243)

Dae yang Oh[1,2], Junseong Hwang[1,2], Geon Kim[1,2], Chanho Kim[3], Jung-Yeol Yeom[1,4]

[1] Korea University, Department of Bioengineering, Seoul, South Korea; [2] Korea University, Interdisciplinary Program in Precision Public Health, Seoul, South Korea; [3] Korea Atomic Energy Research Institute, Daejeon, South Korea; [4] Korea University, School of Biomedical Engineering, Seoul, South Korea

Abstract

Gamma-ray spectroscopy is a fundamental technique for identifying radioisotopes in safety-critical applications. However, in scenarios such as nuclear accidents, high-temperature and high-radiation environments severely degrade photomultiplier tube performance. Conventional temperature compensation systems face physical voltage limits, and prior deep-learning algorithms fail because they require preserved spectral shapes. To overcome these limitations, this study presents a comprehensive strategy to enhance detector stability. First, an active high-voltage control system mitigates initial temperature-induced gain loss. Because this hardware compensation eventually reaches its physical safety limits, the system integrates a deep learning (DL) technique – bidirectional long short-term memory network – to interpret residual spectral distortions, successfully achieving accurate multi-isotope quantification up to 185 °C. Second, to address radiation-induced damage localized within the photomultiplier tube, a targeted active thermal annealing protocol was applied. Following a 1.55 kGy cumulative gamma irradiation, detector output dropped to 23.5% of its baseline. Subsequent thermal annealing of the photomultiplier tube body at 145 °C successfully restored the output to 89.4%. Ultimately, this integration of hardware, software, and active recovery lays a foundation for robust radionuclide identification under concurrent high-temperature and high-radiation constraints.

Simulations of A Novel Time-of-Flight β/γ Transmission Tomography Scanner (#2255)

Robert Carmichael[1,2], **Robert Carmichael**[1,2], Arion Chatziioannou[1,2], Arion Chatziioannou[1,2]

[1] University of California Los Angeles, Department of Molecular and Medical Pharmacology, Los Angeles, USA; [2] University of California Los Angeles, Crump Institute for Molecular Imaging, Los Angeles, USA

Abstract

Large cargo scanning presents a unique challenge for national security. Container size limitations pose challenges to tomographic imaging. This work proposes a new stationary, limited angle tomographic transmission scanner geometry with a unique β/γ source utilizing a pair of fixed flat panel detectors, known as Gamma Tomography (GT). A Gate 10 simulation evaluates the imaging capabilities of the scanner and explores time-of-flight (TOF) and energy discrimination as electronic collimation methods to reduce scattered radiation and improve image quality. A 600 μm thin plastic scintillator sheet encasing 100mCi of ^{60}Co as a near detector locally captures nearly all emitted β particles without significant γ interactions, while a far detector panel of 2 cm thick LYSO crystals captures the ~1.25 MeV energy ^{60}Co γ photons. Both panels were simulated as 50x80 cm with a thin, 2 cm thick, multi-material test object consisting of water, aluminum, titanium, steel, and uranium in the center of the field of view. The same simulation dataset was reconstructed with/without two separate electronic collimation schemes: valid coincidences with a 100 keV energy window around the ^{60}Co photopeaks, and valid coincidences with a 100 ps time resolution. Despite the short acquisition time (18sec), reconstructed images are low noise, with all objects visible above background and distinguishable. The images show attenuation coefficient under-estimation, due to object scatter. TOF and energy discrimination underestimate μ values by 25.8% and 34.3% respectively, but a large dynamic range and very high SNR in μ value is achieved for all reconstructions (SNR-water: 46, SNR-Uranium: 1369). Using time information in lieu of energy allows events scattered in the detector to be used to improve image quality and SNR, but further investigation will include achievable time resolution, panel construction, and source geometry optimization.

Revealing Disorder Faster: Detector Upgrades for SANDALS-II (#2826)

Sarah E. Mann, **Sarah E. Mann**, Nigel J. Rhodes, Nigel J. Rhodes, Erik M. Schooneveld, Erik M. Schooneveld, Giacomo Mauri, Giacomo Mauri, Jack Day, Jack Day, Oliver L.G. Alderman, Oliver L.G. Alderman, Terri-Louise Hughes, Terri-Louise Hughes, Daniel T. Bowron, Daniel T. Bowron, G. Jeff Sykora, G. Jeff Sykora

STFC, ISIS, Harwell Campus, UK

Abstract

SANDALS-II is an instrument being developed at the ISIS Neutron and Muon Source as a next generation diffractometer for the study of amorphous and liquid materials. This upgrade will deliver count rates up to 11 times higher than the existing SANDALS instrument and will significantly expand its scientific capabilities. This work focuses on developments of a large area scintillator detector that are essential for achieving enhanced performance. Scintillation detectors for SANDALS-II will cover a solid angle of 0.67Ω, 2.4 times greater detector coverage than the current instrument. These detectors are required to have high efficiency, particularly at higher neutron energies (short wavelengths), which is achieved using a unique design employing tiles made from alternating layers of glass and scintillator. Scintillator and glass options are explored to optimise detector and instrument performance. Different low Li and B content glasses were tested to determine the most suitable option for the instrument that provides good neutron transmission while maintaining affordability. The ratio of ZnS:Ag to ^{6}LiF in the scintillator will be altered from 4:1 to 2:1 to enhance neutron absorption and therefore detection efficiency. At 30eV (0.05Å) this offers a 60% improvement in detection efficiency. The applicability of low-afterglow scintillator, ZnO:Zn/^{6}LiF, for use in SANDALS-II is also explored. ZnO:Zn/^{6}LiF is shown to offer a 2x increase in count rate capability over ZnS:Ag/^{6}LiF, but a 6% lower neutron detection efficiency. As the reduction in efficiency using ZnO:Zn/^{6}LiF is modest, this alternative scintillator offers a viable solution for the high count rate regions of SANDALS-II. With optimised glass and scintillator selection, the performance required for the upgraded instrument can be delivered. This will enable faster measurements, smaller sample studies, and time resolved experiments, making SANDALS-II a world leading disordered material neutron diffractometer.

Characterization and Radiation Damage Mitigation of Silicon Photomultipliers for Low Earth Orbit Applications (#1902)

Shideh Davarpanah, On behalf of NUSES Collaboration

Université de Genève, Département de physique nucléaire et corpusculaire, Genève, Switzerland

Abstract

Silicon photomultipliers (SiPMs) are attractive photosensors for space applications because of their compact size, low cost, low operating voltage, high photon detection efficiency (PDE), and single-photon sensitivity. Their use in space applications, however, is limited by radiation-induced increases in dark count rate (DCR). This work presents the characterization and radiation tolerance study of FBK NUV-HD-MT SiPMs for the focal plane of the Terzina Cherenkov telescope onboard the NUSES mission, which will operate in a Sun-synchronous low Earth orbit (LEO) at an altitude of approximately 550 km. Devices with micro-cell sizes ranging from 25 to 50 μm were evaluated through a comprehensive characterization campaign comprising static (current-voltage), dynamic (noise and pulse-shape), and optical (photon detection efficiency) measurements to identify the sensor configuration best suited for this application. The 30 μm bare sensors were selected as the optimal solution, achieving a PDE greater than 50% at 400 nm, optical cross-talk below 2%, and a DCR below 60 kHz/mm^2 at 10 V overvoltage. The radiation environment was modeled using SPENVIS, and dose deposition in the focal plane was evaluated with Geant4 simulations. In parallel, radiation effects were investigated experimentally through two irradiation campaigns: a 50 MeV proton beam test and electron exposure using a Sr-90 source. Proton-induced damage produced a significant increase in leakage current and DCR, while electron-induced degradation was substantially smaller. Temperature-dependent measurements were used to extrapolate in-orbit performance and to evaluate recovery through thermal annealing. The results indicate that performing periodic annealing cycles at temperatures above 50°C can reduce the radiation-induced current by up to 40% after approximately 84 hours, helping preserve detector performance over the three-year mission.

Graphene Photodetectors for Vacuum-UV Through Visible Wavelengths (#3124)

Alec Lindman[1], Marcos Turqueti[1], Lisa Schlueter[1], Gabriela R. Araujo[2]

[1] Lawrence Berkeley National Laboratory, Berkeley, USA; [2] University of Zurich, Zurich, Switzerland

This work was supported by the U.S. Department of Energy through the Laboratory Directed Research and Development program.

Abstract
Many experiments rely on measuring vacuum-ultraviolet light, which is emitted in situations as diverse as scintillation in cryogenic liquid noble gases (126.8 nm in argon) and laser spectroscopy of atomic hydrogen isotopes (121.6 nm). Graphene-monolayer photodetectors offer several attractive traits: they are naturally thin, sensitive to a broad range of wavelengths, relatively simple to fabricate (including with integrated readout circuitry with the same process), and can be made on flexible substrates. We present measurements with visible and UV light down to 115 nm, including at low intensity and with fast pulses, of graphene field-effect transistors (GFETs) of various sizes up to 2 mm square fabricated on silicon. These detectors show promise for experiments from neutrinoless double beta decay searches to absolute neutrino mass measurements, as well as dark-matter searches or other VUV-detection applications.

FPGA-Based Real-Time SiPM Emulator with Sub-Nanosecond Temporal Quantization (#1987)

Andrea Abba[1], Stefano Carsi[1], Francesco Caponio[1], Edoardo Proserpio[1,2], Valentina Arosio[1]

[1] Nuclear Instruments SRL, Lambrugo, Italy; [2] Università dell'Insubria, Como, Italy

Abstract
This work presents a real-time FPGA-based Silicon Photomultiplier (SiPM) detector emulator capable of reproducing physically accurate detector waveforms at 16-bit resolution and 2.5 GS/s analog output rate. The proposed architecture combines microscopic event simulation with a temporally quantized event-streaming model, enabling real-time waveform synthesis directly inside FPGA logic while drastically reducing bandwidth requirements compared to traditional waveform streaming approaches. The emulator separates event generation from signal shaping: software layers generate timestamped photon-hit sequences derived either from analytical distributions, Geant4 simulations, or SimSiPM microscopic detector models, while the FPGA reconstructs the analog waveform through parallel Infinite Impulse Response (IIR) filter banks implementing the SiPM transfer function; a look-ahead recursive transformation enables II = 1 operation across all banks at 156.25 MHz, consuming approximately 235 DSP48E2 slices. A multi-phase temporal quantization architecture provides 0.8 ns effective timing precision using a 156.25 MHz fabric clock and eight temporal sub-phases. Experimental validation demonstrates excellent agreement between hardware-generated waveforms and analytical as well as SimSiPM-generated references, including pile-up scenarios with overlapping scintillation events reproduced through linear superposition. The prototype operates with an end-to-end latency of approximately 83 ns.

Abstract

Reliable long-term monitoring in nuclear decommissioning facilities is hampered by the absence of permanent power infrastructure and by the radiation fields that degrade conventional electronics. We present a scintillator-photovoltaic converter that captures ambient gamma radiation and transforms it into electrical energy sufficient for periodic wireless data transmission. The converter pairs a 750 cm³ CsI(Tl) crystal with a compact GaInP photovoltaic array mounted on a single end face, following a "large absorber, minimal semiconductor" strategy.) On-site evaluation inside a contaminated-material storage building at the Fukushima Daiichi Nuclear Power Plant (~35 mSv/h) produced 273 nW per module. Two parallel modules, combined with ultra-low-power energy management and a sub-GHz radio, achieved seven autonomous transmission bursts totaling 32 packets over a 30 m link during a three-hour observation window—without any external power supply or dedicated radioactive source.

Abstract

Polarization observations in extreme ultraviolet (EUV) band have not yet been achieved because it remains technically difficult to develop wide-field EUV detectors with sufficient sensitivity. However, EUV polarization measurements are expected to provide important insights into the emission mechanisms of gamma-ray bursts (GRBs) and ultraviolet flashes associated with supernova explosions. In this study, we propose a novel EUV polarimeter based on Lobster-Eye Optics (LEO), which combines a wide field of view with polarization sensitivity. Optical simulations show that EUV reflectivity on metal surfaces strongly depends on polarization. For example, at 40 eV and an incident angle of 75° on a gold-coated mirror, the reflectivity is about 40% for p-polarization and 60% for s-polarization, respectively. This difference produces an asymmetric cross-shaped image on the focal plane detector depending on the polarization direction. To verify this principle, we developed a test chamber and conducted a synchrotron radiation experiment using a gold-coated mirror and a microchannel plate (MCP) detector. By rotating the mirror around the beam axis, we measured the modulation of the MCP count rate and evaluated the detector modulation factor. The experimental results are presented and discussed in this paper.

Fast or Adapt: Proportional Gas in γ-ray Fields (#1278)

Jakub Prchlik, Eric Yokie, Arlo Petitjean, David O'Connor

Reuter-Stokes, LLC, Twinsburg, USA

Abstract

Background γ-ray fields complicate neutron measurements for Nondestructive Assay (NDA) of Nuclear Materials and the next generation of advanced reactor designs, including non-light water (non-LWR) and Small Modular Reactors (SMRs). Neutron sensitive proportional counter design for high γ-ray fields often focus on optimizing ion collection time and integrating low-Z materials. In these counters, the metal cathode produces most of the Compton scattered electrons, which deposit unwanted energy and signal in the gas. The long path length for Compton electrons in the counter gas means the counter gas pressures may be optimized to increase the ratio of ion-to-electron energy deposition. Here we present gas mixture and pressure optimization for ion-to-electron energy deposition using SRIM simulations. The simulation output is then tested experimentally for its effect on neutron sensitivity in γ-ray fields between 1 R/Hr and 100 R/Hr. The ion-to-electron energy deposition ratio shows promise as an additional design consideration for neutron sensitive proportional counters in γ-ray fields, even though the experimentally measured optimum pressure of 0.5 atm for He/N_2 95/5 is lower than the simulated optimum pressure. Future experiments with a current sensitive preamplifier (CAEN A1427) will improve neutron counting for 1 to 100 R/Hr γ-ray fields.

Development of a Monte Carlo Simulation–Based Analysis Technique for High-Pressure Ionization Chambers (HPIC) (#1858)

Kyeong Hyeon Sung[1], Chul Hee Min[1], Jung-Ki Shin[2]

[1] Yonsei University, Department of Radiation Convergence Engineering, Wonju, South Korea; [2] NeosisKorea, Daejeon, South Korea

This work was supported by the Nuclear Energy International Joint Research Project through the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (MSIT) (No. RS-2025-25396349).

Abstract
High-pressure ionization chambers (HPICs) are widely used for radiation monitoring owing to their high sensitivity and mechanical robustness. However, under low-dose conditions, the inherently small signal results in a low signal-to-noise ratio, making accurate characterization of detector response challenging. Therefore, detailed analysis of radiation interaction and charge transport processes in the detector is required for accurate characterization and optimization of HPIC performance. In this study, a simulation framework was developed to investigate and optimize the signal response characteristics of HPICs. A coupled simulation framework integrating Geant4 and Garfield++ is used to model the full signal formation process, including radiation dose deposition and charge transport under applied electric fields. A Kyocera HPIC was used to measure the current response as a function of applied voltage under irradiation from a 95 μCi Cs-137 source. In the Geant4 simulation, the HPIC geometry was modeled to calculate the spatial distribution of dose deposition within the gas volume, which is subsequently converted into ion pair distributions using the W-value. The electric field is modeled in Garfield++ to simulate charge transport under applied voltages, enabling the calculation of the resulting current response. The collected charge in the anode shows a plateau behavior at approximately 64.2 pA, while the experimental results exhibit a saturation around 54.8 pA. It is predicted that the discrepancy is attributed to additional physical effects such as ion recombination, feedthrough effects, and leakage currents. These findings demonstrate that the proposed approach provides a reliable framework for accurate analysis and optimization of HPIC.

High Granularity Readout Time Projection Chamber R&D for Future Circular e+e- Colliders (#2530)

Huirong Qi[1,2], Maksym Titov[2], On behalf of Linear Collider Time Projection Chamber International Collaboration

[1] Institute of High Energy Physics, CAS, Beijing, China; [2] Linear Collider Time Projection Chamber International Collaboration, Hamburg, Germany

Abstract
A worldwide Lepton Collider Time Projection Chamber community of the physicists was working to realize an exceptional physics program of the energy-frontier, electron-positron collision, especially for Future Circular Collider (FCC-ee), Circular Electron Positron Collider (CEPC) and the International Linear Collier (ILC). In all proposed detector concepts, the Time Projection Chamber (TPC) serves as the main tracking detector, complemented by the

silicon tracking detectors both inside and outside the TPC, all embedded within a 3 T solenoid field. Many extensive R&D program for the track detector has been developed within the collaboration of LCTPC.
TPC performance is satisfactory in Higgs mode, but the high luminosity Z pole running poses substantial technical challenges. Based on MDI background simulation data to study ion-induced space charge effects, we have conducted a detailed assessment of TPC technical challenges and potential solutions, particularly under the high luminosity Z pole running conditions. In this talk, the feasibility and update progress of high precision TPC as the main track detector for e+ e− collider will be presented. TPC detection aims the good separation power with the cluster counting to be considered and the simulation results of the pad/pixelated TPC technology will be given. Compared with the pad readout using the simulation, the high granularity readout TPC options will obtain the better spatial resolution of single electrons, the very high detection efficiency in excellent tracking and good PID performance (less than 3σ). A large prototype TPC in a 1.0T magnetic field, which allow to accommodate up to seven identical Micro Pattern Gaseous Detector (MPGD) readout modules of the TPC being studied using the 5GeV electron beam at DESY, we will present the track reconstruction performance results and summarize the next steps of the pad/pixelated TPC technology for the future lepton colliders.

A Semi-Analytical Method for Sensitivity Estimation of Parallel-Plate Boron-Coated Ionization Chambers (#3076)

Peng Tang

tsinghua university, Institute of Nuclear and New Energy Technology, beijing, China

Abstract
This paper presents a semi-analytical method for sensitivity estimation of multilayer parallel-plate boron-coated ionization chambers. The model combines: (1) an overlap-geometry calculation for the distribution of crossed boron layers under oblique incidence, and (2) a microscopic-simulation-based depth-response function for single-layer effective signal generation. By coupling geometric crossing statistics, boron attenuation, and depth response, detector sensitivity can be rapidly evaluated versus incidence angle, boron thickness, and plate spacing. Compared with Geant4, the method reproduces both trend and magnitude of angular sensitivity, with better agreement at large angles. The framework is suitable for fast parameter screening before high-fidelity simulation.

A New Efficient n-γ Pulse Shape Discrimination Technique for Fast Scintillation Detectors (#1149)

Stefano Riboldi[1,2], Agnese Giaz[2], Sergio Brambilla[2], Ciro Boiano[2]

[1] *Università degli Studi di Milano, Fisica, Milano, Italy;* [2] *INFN, Milano, Milano, Italy*

Abstract

Pulse shape discrimination (PSD) is an effective technique for identifying the interacting particle (e.g., gamma rays or neutrons) in scintillation detectors.

In the simplest cases (e.g., the Cs_2LiYCl_6 scintillator, showing a large difference between gamma and neutron signals), the PSD procedure can be performed using the "charge integration" (CI) method, based on rectangular weighting functions. However, for scintillators with smaller differences in signal shape (e.g., the $LaCl_3$:Ce scintillator), different methods must be used.

Moreover, when digital acquisition systems are used, sampling the photodetector's analog signal at a finite time step can significantly affect the PSD results. Indeed, apart from the effects of electronic and quantization noise, the main cause of overlapping of the PSD regions of interest (ROI) of fast scintillator signals processed in the time domain is the temporal variability (ΔT) of the sampling comb relative to the onset of the analog pulse. In the case of relatively high DAQ's acquisition frequency (e.g., 500 MHz), increasing it further to mitigate this issue is not practical, and alternative techniques must be used.

One solution is to proceed via the absolute value of the discrete Fourier transform (DFT) of the signal, which completely solves the temporal variability issue, though at the cost of significant computational burden.

This paper presents a new analysis technique that solves the problem with a negligible computational overhead, making it especially suitable for online applications, by just linking the information on the time shift ΔT to the detector signal, and linearly filtering the whole dataset.

The filter weighting function is determined with the DPLMS optimal filter synthesis algorithm, employed here for the first time for this purpose.

The PSD results obtained with this technique, suitable as well for energy and time estimations, are here shown for experimentally acquired $LaCl_3$:Ce scintillator signals.

Abstract

Near infrared (NIR) emitting scintillators have attracted attentions recently for radiation monitoring at high dose fields. In this work, NIR scintillation properties of Yb3+ and Nd3+ doped fluorapatite (Ca10(PO4)6F2, FAP) transparent ceramics with different doping concentration were investigated. These materials have been originally developed for laser applications. The most famous laser material, Nd:YAG transparent ceramic, can show good scintillation performance both UV-VIS emission and NIR emission, and following such a study, good performance can be expected in FAP transparent ceramic. When X-rays were irradiated, they exhibited 1000 nm (Yb) and 1064 (band) emission bands, and their scintillation decay time resulted several micro hundreds s. The most important property for high dose field monitoring, the lower detection limit (LDL), was investigated by coupling with InGaAs photodiode. Yb and Nd-doped FAP showed 1.2 and 0.6 mGy/hr, respectively. In the conference, scintillation properties as well as photoluminescence properties will be presented, and compared with other NIR emitting scintillators.

Abstract

Halide perovskites are promising scintillator materials for radiation detection and medical imaging because of their excellent optical and scintillation properties. Since the surface quality of single-crystal scintillators strongly affects light extraction and detector performance, polishing is an essential step in scintillator fabrication. However, conventional wet polishing processes are not suitable for water-sensitive crystals such as $Cs_3Cu_2I_5$ (CCI). In this work, hydrophobic solvents were investigated as polishing media for water-sensitive CCI single crystals. Three hydrophobic solvents—squalane, silicone oil, and mineral oil— were used as dispersion media for 1 μm alumina abrasives, followed by toluene rinsing after polishing. Among them, squalane showed the best polishing performance, yielding the lowest surface roughness (R_q=17.29 nm), the highest transmittance of 78.21%, and the narrowest rocking-curve FWHM of 0.025°. In addition, sequential polishing in squalane using P2000 sandpaper, P4000 sandpaper, and 1 μm alumina enhanced the light yield and improved the energy resolution from 6.53% to 5.83%. These results identify squalane as a promising polishing medium for water-sensitive halide perovskite scintillators.

Abstract

Time-of-flight positron emission tomography (ToF-PET) has boosted PET image quality significantly in the last years. During its first inception it was built with cross-luminescent BaF_2 crystals, which have since been replaced by LYSO. Recently, cross-luminescence has regained popularity with new scintillators being developed. However, BaF_2 and the recently developed Cs_2ZnCl_4 could not improve on the LYSO state-of-the-art coincidence time resolution (CTR) (56 ps for 2x2x3 mm³ and 95 ps for 3x3x19 mm³). As Cs_2ZnCl_4 shows a significant Cherenkov production, we combined it with the DIGILOG approach to boost its timing performance. The DIGILOG approach segments the sensor into μSiPMs and has shown an improved timing performance for BGO due to its Cherenkov

radiation and an improved SPTR. Here, we simulated a 3x3x3 mm³ and a 3x3x20 mm³ Cs_2ZnCl_4 crystal coupled to seven different µSiPM arrays. The simulation included noise factors like dark counts, cross-talk, SPAD dead time and analog noise. It was designed with a PDE of 60 % and an SPTR of 25 ps. This resulted in an improved CTR of 34+/-4 ps for an array of 20x20 µSiPMs coupled to a 3x3x3 mm³ Cs_2ZnCl_4 crystal compared to the non-segmented SiPM at 48+/-3 ps. Furthermore, for the 3x3x20 mm³ crystal, a CTR of 64+/-4 ps was reached with a 10x10 µSiPM array, while the non-segmented SiPM showed a CTR of 84+/-3 ps. The results of the segmented SiPMs improve on the LYSO state-of-the-art. Additionally, they demonstrate that the DIGILOG SiPM approach improves timing performance not just for BGO, but also for other scintillators with high Cherenkov yield, ultra-fast emission and low light yield. We also provide motivation to optimize sensors for Cs_2ZnCl_4, which could enable better timing performance than the LYSO state-of-the-art.

Temperature Dependence of Pulse Shape Discrimination in SiPM-Based EJ-276D Detectors (#1585)

Jacob W. Fritchie, Angela Di Fulvio, Gabriella Gariazzo, Grant Roche, John Leland

University of Illinois Urbana-Champaign, Nuclear, Plasma, and Radiological Engineering, Urbana, USA

This work is funded in-part by Sandia National Laboratories (SNL) LDRD Award 2308289. SNL is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration (NNSA) under contract DE-NA0003525. This research was performed under appointment to the Nuclear Nonproliferation International Safeguards Fellowship Program sponsored by the U.S. NNSA's Office of International Nuclear Safeguards.

Abstract

The temperature dependence of pulse shape discrimination performance was investigated for three commercial silicon photomultiplier technologies coupled to an EJ-276D organic scintillator. Measurements were conducted at 22 °C, 30 °C, 40 °C, and 50 °C using PuBe sources. Pulse shape discrimination was quantified using the tail-to-total ratio and figure of merit. For all devices, the figure of merit increased at 30 °C. The Broadcom device exhibited the highest performance, increasing from 1.12 at 22 °C to a maximum of 1.17 at 30 °C before decreasing to 0.76 at 50 °C. The Onsemi and Hamamatsu devices showed smaller improvements, with figure of merit values increasing from 0.86 to 0.89 and 0.84 to 0.90, respectively, between 22 °C and 30 °C. At 50 °C, all devices exhibited reduced performance due to increased silicon photomultiplier thermal noise. Temperature-dependent changes in pulse shape were observed, with increasing temperature producing faster decay and modifying the balance of prompt and delayed scintillation light, improving neutron-gamma separation at intermediate temperatures. Despite degradation at higher temperature, all devices maintained effective discrimination up to 50 °C. These results demonstrate that silicon photomultiplier-based detectors are capable of robust neutron-gamma discrimination at elevated temperatures relevant to safeguards applications.

Los Alamos National Laboratory is managed by Triad National Security, LLC for the U.S. Department of Energy's NNSA.

Abstract

Cerium-doped gadolinium gallium aluminium garnet (GAGG:Ce) is a novel scintillator with excellent scintillation properties. It is suitable for use in various basic science research and applications. Because the scintillation light is quenched for charged particle detection, it is necessary to use beams from accelerators to calibrate the energy response. Measurements of energetic charged particles incident on three GAGG:Ce crystals were performed using accelerated protons, ^{4}He, and ^{12}C at 0°C and 20°C in consideration for detecting charged particles in the earth's

radiation belts for space weather modeling and for deploying in dosimetry devices in ion therapy, respectively. The Birks factor which quantitatively describes the extent of quenching was deduced from the experimental data. For all three GAGG:Ce scintillators, the Birks factor decreases with the atomic number Z of the incident ions. Furthermore, less light quenching, a smaller Birks factor, was observed for GAGG:Ce at 0°C. The quenching for the Mg-codoped GAGG:Ce which has a shorter decay time constant, was found to be less temperature dependent compared to the other two GAGG:Ce crystals.

Facile, scalable and high-yield synthesis of zero-dimensional copper halide $Cs_3Cu_2Cl_5$ scintillator with near-unity quantum yield for high-resolution X-ray imaging applications (#1659)

Young Seung Choi[1], Jaeyoung Im[2], Kang Heo[3], Sung Oh Cho[2], Bo Kyung Cha[4], **Byungha Shin**[1]

[1] KAIST, Materials Science and Engineering, Daejeon, South Korea; [2] KAIST, Nuclear and Quantum Engineering, Daejeon, South Korea; [3] Viewworks, Anyang, South Korea; [4] KERI, Ansan, South Korea

Abstract
Metal halide perovskites, particularly copper halide variants, have emerged as promising scintillators owing to their large Stokes shift, high photoluminescence quantum yield (PLQY), and efficient radioluminescence. Here, we demonstrate a dioxolane-mediated reaction synthesis as a simple, scalable, and high-yield strategy for producing $Cs_3Cu_2Cl_5$ powders with near-complete conversion. By employing low-polarity yet water-miscible dioxolane as the reaction medium together with an aqueous H_3PO_2 additive, the solubility imbalance between the precursors inherent to low-polarity solvents is effectively addressed. This approach enables stoichiometry-controlled dissolution–precipitation under a low-polarity reaction environment and the formation of phase-pure $Cs_3Cu_2Cl_5$ powders with near-unity PLQY. The powders show bright green emission at ~530 nm and retain over 80% of their initial efficiency after 300 days of ambient storage without encapsulation, demonstrating remarkable intrinsic stability. $Cs_3Cu_2Cl_5$-based composite films deliver an ultrahigh light yield of ~98,000 photons MeV^{-1}, greatly surpassing that of commercial scintillators such as Gd_2O_2S and CsI:Tl, and exhibiting excellent dose linearity and long-term irradiation stability. When integrated into commercial flat-panel detectors, the $Cs_3Cu_2Cl_5$-based composite films successfully enabled high-quality 2D radiographic and 3D computed tomography imaging, directly verifying their compatibility with existing X-ray detection systems. This facile and efficient synthesis, together with

the demonstrated device-level imaging performance, highlights $Cs_3Cu_2Cl_5$ as a scalable and practical candidate for next-generation X-ray scintillators.

Spectral-feature-based radionuclide and radiation-type discrimination using a plastic scintillation fiber detector for in-situ pipe measurements

(#1767)

Tomohisa Abe[1], Takamasa Nakasone[2], Tsutomu Yamada[2], Marina Kanno[3], Yuki Morishita[1]

[1] Japan Atomic Energy Agency, Collaborative Laboratories for Advanced Decommissioning Science, Minamisomashi, Japan; [2] Japan Radiation Engineering Co.,Ltd., Hitachishi, Japan; [3] PESCO Co., Ltd., Minatoku, Japan

Abstract

A capillary-type plastic scintillation fiber (PSF) detector combined with a multi-channel analyzer (MCA) was investigated for radionuclide and radiation-type discrimination in in-situ pipe measurements. Plastic scintillators generally exhibit poor energy resolution, resulting in broadened spectra that complicate conventional peak-based identification. In this study, spectral features including the Compton edge (CE), endpoint, and centroid were extracted from β- and γ-ray spectra obtained using Sr-90/Y-90 and Cs-137 sources. The positional dependence of these features along the fiber was evaluated, and significantly reduced variation compared with previous studies was achieved by introducing a reflective structure at the fiber end. In addition, radiation-type discrimination under mixed β/γ conditions was investigated using a stainless-steel (SUS) cover to suppress β-ray components. The results demonstrated that the extracted spectral features remained stable against source position and that condition switching using the SUS cover enabled practical discrimination of β and γ components. These findings indicate that the proposed method is applicable to contamination assessment in confined environments such as piping systems.

Investigation of Coincidence Time Resolution in BaF_2:Y Scintillators for TOF PET Applications (#1798)

Heejong Kim[1], Junfeng Chen[3], Jing Zhang[3], Jiawei Xu[3], Subramanian Sundramoorthy[2], Yingjie Wang[1], Chin-Tu Chen[1], Chien-Min Kao[1]

[1] University of Chicago, Department of Radiology, Chicago, USA; [2] University of Chicago, Department of Radiation and Cellular Oncology, Chicago, USA; [3] Chinese Academy of Sciences, Shanghai Institute of Ceramics, Shanghai, China

Abstract

We are investigating BaF_2:Y scintillators for TOF-PET applications. BaF_2 exhibits an ultra-fast scintillation component with a 0.6 ns decay time produced through cross-luminescence, making it an attractive material for achieving coincidence time resolutions below 100 ps. Recent advances in Vacuum-Ultraviolet (VUV) SiPMs, which provide high photon-detection efficiency in the deep-UV range, have made it increasingly feasible to reliably detect this fast component. In addition to the fast emission, BaF_2 also contains a slow scintillation component with a decay time of approximately 600 ns. This slow component can be substantially suppressed through doping—for example, BaF_2:Y, produced via yttrium doping. Effective suppression of the slow component is essential for applications requiring high count-rate capability, excellent timing performance, and minimal pulse pile-up, such as TOF-PET. In this work, we investigated the coincidence time resolution (CTR) of BaF_2:Y scintillators. The BaF_2 and BaF_2:Y crystals used in this study were grown and polished by the Shanghai Institute of Ceramics (SIC), China. For the BaF_2:Y samples, the yttrium concentration was set to 2 at%, which suppressed the slow component by approximately a factor of four while leaving the fast-component light yield unaffected. Hamamatsu S13370 VUV-MPPCs were used to detect the fast scintillation component. Pairs of BaF_2 and BaF_2:Y crystals with dimensions 2 × 2 × 3 mm^3 were optically coupled to S13370 VUV-MPPCs and irradiated with a ^{22}Na source placed between them in a coincidence setup. We measured CTR values of 86 ps for BaF_2 and 96 ps for BaF_2:Y. These initial results are highly promising, and we anticipate further improvements in CTR with a more optimized experimental setup. Here, we report our preliminary findings.

This work was supported by the Spanish Government under grant PR38/23-HISTARS(MRR)

Abstract

Depth of interaction (DOI) effects can affect the timing response of scintillation detectors due to variations in optical photon transport inside the crystal volume. In this work, DOI-dependent timing measurements were performed using a 1”×2” $LaBr_3$ scintillation detector coupled to a photomultiplier tube (PMT) within the framework of the HiSTARs project. A ^{22}Na source was positioned at different locations along the crystal axis in coincidence with a fast SiPM-based reference detector, and signals were acquired using a DRS digitizer operating at 5 GS/s. The present study focuses on the comparison between interactions occurring close to the PMT side of the crystal and interactions occurring close to the opposite side. Coincidence timing distributions show a systematic shift of approximately 300 ps in the centroid position between both irradiation configurations. Coincidence timing resolutions of 287 ps and 268 ps FWHM were obtained for the two positions, respectively. The observed behavior is consistent with differences in optical photon propagation paths and light collection timing inside the scintillator. Although DOI effects introduce measurable timing shifts, the overall degradation of the timing resolution remains moderate for the studied configurations. Additional irradiation geometries and analysis conditions are currently under study in order to obtain a more complete characterization of DOI effects in long $LaBr_3$ scintillation detectors.

Development of Mo-Doped Cs_2HfCl_6 for Dosimetry in High Dose-Rate Environment (#2267)

Shinichiro Kondo[1], Chihaya Fujiwara[2,3], Akihiro Yamaji[3], Shunsuke Kurosawa[3,4]

[1] Nagoya University, School of Engineering, Nagoya, Japan; [2] Tohoku University, Department of Materials Science, Graduate School of Engineering, Sendai, Japan; [3] Nagoya University, Graduate School of Engineering, Nagoya, Japan; [4] Osaka University, Institute of Laser Engineering, Osaka, Japan

Abstract

In order to accomplish rapid and safe decommissioning of Fukushima Daiichi nuclear power plant, the remote and real-time dosimeter was required. To address this issue, detector systems comprising a scintillator coupled to an optical fiber have been proposed. In this system, emission wavelength of the scintillator itself should be in the near-infrared (NIR) band, to spectrally discriminate the scintillation signal from the Cherenkov component generated within the optical fiber itself. Therefore, in this study, we focus on Mo doped Cs_2HfCl_6 as the scintillator with NIR emission wavelength and high atmospheric stability. The Mo doped Cs_2HfCl_6 scintillators were grown via melt solidification method. The result of powder X-ray diffraction pattern suggested that the single phase of Mo: Cs_2HfCl_6 were successfully obtained. Furthermore, the emission wavelength of Mo doped Cs_2HfCl_6 was shifted to 900nm from 420 nm of host emission of C_2HfCl_6. These results indicate Mo: CHC is the promising scintillator for the real time remote monitoring system with optical fiber.

From $LaBr_3$:Ce to $Cs_2LiLa(Br,Cl)_6$:Ce Mixed-Halide Elpasolites: Tailoring Scintillation Response for High-Precision Gamma-Ray and Neutron Detection (#2321)

Zhuochen Cai[1], Ziang Yin[1], Xianggang Zhang[1], Zhe Kang[2], Jinbo Liu[2], Qinghua Zhao[1], Tao Wang[1]

[1] Northwestern Polytechnical University, State Key Laboratory of Solidification Processing, Xi'an, China; [2] Crystalab Corporation Ltd, Xi'an, China

Abstract

Halide scintillators provide a flexible material platform for detectors requiring high gamma-ray energy resolution, fast response, and, in lithium-containing compounds, intrinsic neutron sensitivity. This work presents CrystaLab Co., Ltd.'s compositional-engineering route from $LaBr_3$:Ce gamma-ray scintillators to $Cs_2LiLa(Br,Cl)_6$:Ce (CLLBC) mixed-halide Elpasolites for combined gamma-ray and neutron detection. Packaged $LaBr_3$:Ce detector modules demonstrate high-resolution gamma-ray spectroscopy, with a representative energy resolution of 2.37% at 662 keV and product specifications below 3% at 662 keV. $CeBr_3$ detectors provide a low-background lanthanide-halide

option with energy resolution below 4.5% at 662 keV. By introducing Li and tuning the Br/Cl halide sublattice, $Cs_2LiLaBr_6$ (CLLB) and CLLBC extend the platform to neutron-sensitive dual-mode detection with neutron-gamma pulse-shape discrimination (PSD). CLLB products provide gamma-ray energy resolution below 4.5% at 662 keV and room-temperature neutron-gamma figure of merit (FOM) values >1.2, while optimized 1-inch CLLBC crystals achieved 3.09% energy resolution at 662 keV and FOM = 2.1. These results show how halide composition, crystal growth, and detector integration can tailor scintillation response from high-precision gamma-ray spectroscopy toward compact mixed-field radiation detectors.

Application of neutron sensitising layers to plastic scintillator (#2414)

Jack R. Hitchens, Chris Allwork, Shivani L. Chauhan, Tom Crane, Tom Heather, Matt P. Taggart

AWE Nuclear Security Technologies, Reading, UK

Abstract

Eljen plastic scintillator disks have been coated with layers of neutron sensitiser in a systematic study on the thickness of neutron detection layers. Here we discuss the impact of enhancing standard plastic scintillator (PVT) with coatings containing both lithium and boron isotopes. The application of these layers enhances the material to provide a mechanism for detecting neutron radiation. A systematic study was performed to assess the impact of sensitiser thickness on neutron detection efficiency and neutron-gamma pulse shape discrimination (PSD) performance. Samples were exposed to the mixed radiation fields of a ^{252}Cf source, and a sample of plutonium. The results demonstrate clear neutron-gamma discrimination in sensitised samples, with measured figures of merit in excess of 3 recorded for optimised lithium-rich coatings. This is comparable performance to established dual-mode detectors. These findings show that thin, externally applied neutron-sensitising layers provide an effective route to enhancing the performance of conventional plastic scintillators. This approach may offer a low-cost means of upgrading existing detector systems in nuclear security applications.

Micropower Generation and Radiation Detection with Cr-doped Al_2O_3 Transparent Ceramics (#2416)

Noriaki Kawaguchi, Keita Miyajima, Kai Okazaki, Takumi Kato, Daisuke Nakauchi, Takauyuki Yanagida

Nara Institute of Science and Technology, Ikoma, Japan

This work was supported by the Cooperative Research Project of Research Center for Biomedical Engineering, Kazuchika Okura Memorial Foundation, Yashima Environment Technology Foundation, Iketani Science and Technology Foundation, and JSPS KAKENHI (22H00309, 24K03197, and 26K03208).

Abstract

We prepared 0.05–1% Cr-doped Al_2O_3 transparent ceramics with a diameter of approximately 10 mm by spark plasma sintering. The samples showed sharp emission peaks at around 700 nm, which matched the sensitivity of typical Si-photodetectors. When the samples were combined with a Si-photodetector and irradiated with X-, α-, and β-rays, currents ranging from picoamperes to nanoamperes were detected. The generated power was maximized when the dopant concentration was around 0.2–0.4 %.

Abstract

An accurate and precise determination of the depth of interaction (DOI) of incident photons in scintillation detectors is paramount to increasing the spatial resolution of positron annihilation tomography (PET) systems. The high number of readout channels is a major source of cost and complexity of such systems, while light sharing multiplexed readouts suffer from edge effects. We have developed a pixelized scintillator detector with DOI capability and 4-to-1 multiplexing utilizing only single-ended readout and light-sharing light guides which can

improve signal-to-noise ratio and mitigate edge effects present in other solutions. The scintillator matrix is coupled to a silicon photomultiplier (SiPM) array on one end and light guides on the other. Adjacent crystals are connected in pairs via light guides to enable light sharing. The scintillation light of these crystal pairs is shared between exactly two SiPM pixels. DOI is determined using the ratio of signals on the two SiPM pixels. Pairing distant crystals on matrix edges avoids edge effects. We present the detector architecture and the results of optical simulations evaluating its DOI capability. The interaction position was swept along the central axis of one crystal and the number of incident photons was recorded in the interaction crystal and in the optically connected crystal. The number of rays incident on the sensor coupled to the interaction crystal is always higher than that of the connected crystal. This enables unambiguous determination of the interaction crystal. The ratio of the number of rays incident on the sensors spans three orders of magnitude and approaches unity as the source gets closer to the light guide. These properties demonstrate a favorable DOI capability of the presented detector configuration.

Abstract
The HIE-ISOLDE Timing Array for Reaction Studies (HISTARS) project at CERN is developing a specialized detector system designed to measure the lifetimes of excited nuclear states. For efficient particle detection, thin square GaGG(Ce) are utilized alongside YSO due to their high density and fast scintillation properties. This work evaluates the performance of GAGG(Ce) crystals coupled with two distinct photosensors: a Hamamatsu R9779 photomultiplier tube (PMT) and an array of four silicon photomultipliers (SiPM) using a custom-designed circuit. These configurations were tested in combination with a $LaBr_3$(Ce) detector to facilitate coincidence measurements. Data acquisition was performed using high-speed digitizer to extract timing and energy information. This article reports on the comparative performance of both readout methods, specifically characterizing pulse shape

discrimination capabilities, energy resolution, and the coincidence time resolution for alpha-gamma events. Although the energy resolution is acceptable and it has a good pulse shape discrimination capability, the measured timing limitations show that the current configuration is not ideal for the HISTARS array. These results will guide the selection of better-suited materials for high-precision timing at HIE-ISOLDE.

Abstract

By measuring the time difference and amplitude ratio of the signals at both longitudinal ends of a triangular prism plastic scintillator through dual-end readout, it is theoretically possible to reconstruct the longitudinal position of an incident muon. This paper presents a cosmic-ray muon collimation device that determines the incident region via triple coincidence and features an adjustable incident area. Using natural cosmic-ray muons obtained with this device, dual-end positioning experiments were carried out on a triangular prism plastic scintillator. The threshold-crossing time and amplitude information were extracted from the complete waveforms and fitted, yielding well-fitted relationship functions of the threshold-crossing time difference and the logarithm of the amplitude ratio with respect to the hit position. Experimental results show that the longitudinal position resolution achieved by this method is 3 cm, confirming the effectiveness of the dual-end readout positioning method in triangular prism plastic scintillator array muon detectors and laying a foundation for future research on lightweight and efficient plastic scintillator array detectors.

[1] India Institute of Technology Roorkee, Department of Physics, Roorkee, India; [2] Bhabha Atomic Research Centre, Technical Physics Division, Mumbai, India

Abstract

Alkali halide scintillators have emerged as promising low-cost alternatives to conventional thermal neutron detectors such as ^{3}He counters, through the incorporation of neutron sensitive isotopes such as ^{6}Li or ^{10}B, owing to their ease of growth and scalability. In this work, single crystals of CsI:Tl incorporating 2% ^{6}Li and varying concentration of Sr as dopants were grown using the Bridgman melt growth method and evaluated for their scintillation and neutron-gamma discrimination characteristics. The radioluminescence spectra are dominated by yellow-green emission from Tl activator sites. Under ^{137}Cs excitation, the light output of the crystals was observed to decrease with Sr incorporation compared to the ^{6}Li-only doped crystal, while the crystal doped with 2% Sr exhibit the best energy resolution of 6.8% at 662keV. The pulse shape discrimination (PSD) studies of the grown crystals demonstrate effective neutron-gamma discrimination, highlighting the potential of these crystals for use in mixed radiation fields and compact radiation system.

Abstract

A series of polyvinyl toluene (PVT)-based scintillators was prepared via thermal polymerization to investigate the effect of the thermal initiator 2,2-Azobisisobutyronitrile (AIBN) on light output. Samples were synthesized both with varying weight percentages (wt%) of AIBN and without AIBN. All samples contained 2% 2,2-diphenyloxazole (PPO) and 0.05% 1,4-bis(5-phenyl-2-oxazolyl) benzene (POPOP), while the concentrations of vinyl toluene and AIBN were varied. The light output of the developed plastic scintillators (PS) was compared to the commercially available PS EJ-267D using the gamma spectrum from a Cs-137 radiation source. The results indicated that samples containing 0.1% AIBN without argon purging, 1% AIBN without purging, and 0% AIBN with argon purging yielded 24.40%, 28.23%, and 40.88% of the light output of EJ-267D, respectively.

Comparative Analysis of Scintillators for TOF-DXA Detectors in the Low-Energy X-ray Region (#3149)

Jiwon Nam, Jiwoong Jung, Sang-hyun Chun, Sena Kwon, Jin Ho Jung, Yong Choi

Sogang University, Department of Electronic Engineering, Intelligent Signal Processing System (ISPS) Laboratory, Seoul, South Korea

This research was supported by the Industrial Technology Innovation Program funded by the Ministry of Trade, Industry and Energy (no. P0030253), by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (no. RS-2023-00280177), and by the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (no. RS-2026-25565373) of the Republic of Korea.

Abstract

TOF-DXA requires simultaneous energy and timing measurement in the low-energy X-ray region (<60 keV). However, the low X-ray energies result in reduced scintillation light output and small detector signals, making timing measurement challenging. The purpose of this study was to evaluate the performance of different scintillators for energy and timing measurement in low-energy TOF-DXA detectors.

An analog front-end circuit was developed for energy and timing measurement in low-energy TOF-DXA detectors. Detector signals in the energy path were amplified transmitted differentially to reduce common-mode noise and signal degradation. For timing path, a high slew-rate amplifier and comparator were used to generate LVDS preserving the rising-edge integrity of detector pulses. Three 3 × 3 × 3 mm^3 scintillators (LYSO, GFAG, and YAP) coupled with a NUV-MT SiPM were evaluated for simultaneous energy and timing measurement. Output pulses were measured using an Am-241 point source to evaluate energy resolution and pulse characteristics. In addition, X-ray spectra were acquired using an X-ray generator operated at 83 kVp and 0.2 mA with a Ce filter to evaluate detector performance in the DXA.

The energy resolutions measured with LYSO, GFAG, and YAP were 25.7%, 24.4%, and 30.9%, respectively. In the timing path, LYSO exhibited the highest slew rate (364.8 MV/s), followed by GFAG (354.9 MV/s) and YAP (220.8 MV/s). LYSO showed the highest peak-to-valley ratios for both the low- and high-energy peaks (3.96 and 1.62, respectively). For the low-energy peak, GFAG and YAP showed PVRs of 3.32 and 2.45, respectively, whereas YAP showed a slightly higher high-energy PVR (1.13) than GFAG (1.02).This overall performance may be attributed to the balanced characteristics of LYSO, which exhibited higher light output than YAP and faster decay time than GFAG.

These results indicated that LYSO was superior to GFAG and YAP for TOF-DXA applications requiring both energy and timing measurement.

Improved Low-Energy Threshold Performance of a Vacuum-Compatible Hybrid Pixel Detector for Soft X-ray Applications (#1007)

Yasukazu Nakaye, Tomonao Inoue, Masaya Oka, Takuto Sakumura, Yasutaka Sakuma, Satoshi Mikusu

Rigaku Corporation, Detector Development Grp., Akishima, Japan

Abstract

We report characterization results of a vacuum-compatible, pre-production hybrid pixel array X-ray detector incorporating a silicon sensor and a low-noise photon-counting readout ASIC, with emphasis on extending the practical low-energy discriminator threshold. Calibration pulse measurements combined with refined noise characterization enabled evaluation of discriminator threshold settings down to approximately 450 eV. Considering measured RMS noise levels on the order of 70-80 e^-RMS, such threshold operation implies practical detectability of soft X-ray photons with energies around 500 eV, although uniform full-field operation at this threshold is not yet expected.

Low-threshold operation was found to be temporally stable, showing negligible threshold drift and no observable degradation of pixel operability during continuous operation over extended periods. Soft X-ray beam validation experiments are planned at the SPring-8 BL17SU beamline. Additional measurements at higher X-ray energies will be conducted at BL32-B2 and BL29XU to support fundamental characterization of detector and ASIC behavior.

The present study focuses on system-level noise correction and threshold optimization using a conventional silicon sensor. Evaluation with alternative sensor technologies, including iLGAD, is foreseen in future work.

This work was supported in part by the Compton Spectrometer and Imager, a NASA Explorer project led by the University of California, Berkeley with funding from NASA, United States under contract 80GSFC21C0059.

Abstract
The Compton Spectrometer and Imager (COSI) is a NASA Small Explorer satellite mission scheduled for launch in August 2027. COSI's imaging capabilities are achieved by reconstructing Compton scattering events within a 2 x 2 x 4 stack of germanium detectors (GeDs). Each GeD contains orthogonal electrode strips on opposite faces of the detector, forming an x-y grid. An incident gamma ray interacts with the GeD by depositing energy in one or more strips on each face that are then read out simultaneously. The "strip pairing" algorithm reconstructs the 2D position of each scatter by comparing the measured energies on pairs of orthogonal strips through a reduced chi square statistic. While simple for a single-site event, the matching becomes more complex when considering multiple scatters within a detector, multiple scatters on a single strip, or charge sharing between neighboring strips. Here, we describe the strip pairing algorithm and how it is implemented into the COSI pipeline. We then test the algorithm's efficacy and use it to demonstrate the imaging and spectral performance of a COSI GeD. Using a ^{137}Cs calibration source and a single test detector, we find that the pipeline reconstructs the source's position and yields an energy resolution of less than 1% full width at half maximum at 662 keV.

Abstract
Semiconductor radiation detectors are often limited due to thermal degradation of their electrical properties: as temperature increases, thermally activated carrier generation and other effects lead to elevated leakage currents and reduced signal to noise ratios. For more extreme environments such as advanced reactors and molten salt environments, detectors which operate at high temperatures are needed. Diamond, with its wide 5.47 eV bandgap, high carrier mobility, and radiation hardness is a promising material. Previous work in literature reported charge collection efficiency degradation in diamond at 230 °C, followed by recovery and stability of operation to 450 °C. However, this result has not been widely validated. This study evaluates three diamond samples of varying thickness at elevated temperatures, reevaluating carrier mobility and charge collection efficiency. Alpha traces at each temperature are analyzed to study the current transients, gaining insight into how thermal variations impact detector performance and mechanisms driving charge transport variation.

Monitoring neutron exposure in hyper-pure germanium detectors with in-situ capture reactions (#1736)

Thomas Round[1], Brendan Green[1], Stephen Croft[1], Joshua Moore[2], Alex Metcalfe[1], Malcolm J. Joyce[1]

[1] Lancaster University, Engineering Department, Lancaster, UK; [2] NSG Environmental, Chorley, UK

We acknowledge the support of NSG Ltd (Chorley, UK) and the UK Nuclear Decommissioning Authority.

Abstract
The potential to monitor neutron exposure in hyper-pure germanium detectors via capture-g reactions in the germanium crystal is explored. The short-lived reactions on ^{70}Ge and ^{74}Ge resulting in g rays in the 130 to 200 keV energy region have been studied in terms of their response to thermalization of neutrons incident on portable, mechanically cooled, reverse-electrode hyper-pure germanium detectors (REGe^{TM}). The relative sensitivity in terms of y rays emitted per unit neutron flux is estimated and a comparison is made with the inelastic response observed at higher energies, the latter often considered as cause of damage in such detectors. We report the potential for

these short-lived reactions to serve as a built-in neutron-sensitive diagnostic for germanium detector use in hot cells and realistic, mixed-field environments.

Pixel Architecture Effects on Neutron-Induced White Spot Generation in CMOS Image Sensors (#1811)

Jihun Jeong[1], Seil Kim[2], Jungman Lim[2], Seungbae Lee[2], Inyong Kwon[1]

[1] Yonsei University, Radiation Convergence Engineering, Wonju, South Korea; [2] Samsung Electronics, Whaseong, South Korea

Abstract

This paper quantifies how pixel structural parameters, specifically pitch, photodiode type, and transfer gate design, independently influence neutron-induced white spot generation in CMOS image sensors. Six sensor families with pixel pitches of 0.64, 0.70, 1.00, 1.12, and 1.20 μm, covering single and dual photodiode configurations and single and dual transfer gate designs, were irradiated with neutrons at the TRIUMF facility across seven cumulative fluence steps up to approximately 7×10^8 n/cm². Ten samples per family were used, with dark-frame measurements performed at each step using eight-frame averaged images. White spot fractions were extracted using a baseline-subtracted delta counting method with Arrhenius-based temperature correction applied to the radiation-induced component. All six families exhibit a clear power-law dependence of white spot fraction on fluence. Spatial analysis reveals a monotonic increase in the 3×3 cluster ratio, defined as the ratio of the summed dark signal increase in neighboring pixels to that of the center hot pixel, from 0.14 at 1.20 μm to 0.24 at 0.64 μm, and this metric remains independent of fluence. A two-stage meta-regression model shows that increasing pitch from 0.64 to 1.20 μm raises the power-law amplitude by 2.12 times, adopting dual photodiode sharing raises it by 2.35 times, and employing a dual transfer gate reduces it by 0.49 times. Furthermore, the model is extended to predict white spot fractions for unmeasured pixel configurations, with potential for radiation-tolerant CIS design.

This study was carried out with support from the INFN CSN5 Call ARCADIA. This work was supported by the European Union's Horizon Europe research and innovation programme under the 1MICRON project – "New Technology for 1 MICRON Resolution Biomedical Imaging" (grant agreement No. 101186826).

Abstract

Monolithic silicon CMOS Sensors represent a considerable step forward in charged particle and photon sensing, and emerge as a promising embodiment for the design of novel deep-silicon photon-counting X-ray Computed Tomography scanners . This work presents the first characterization of the ARCADIA MD3 Fully-Depleted CMOS sensors, which technology is currently the baseline for the development of innovative sensors under the framework of the EIC Pathfinder Open 1MICRON project. We report on the characterisation results using an edge-on geometry and a focused synchrotron X-ray beam at the DESY test facility. The x-rays impinge on the edge of the sensor, increasing the active sensor depth seen by the photons, which consequently improves the quantum efficiency with respect to a face-on configuration. A 37 keV focused beam incident parallel to the sensor surface allowed scans along the two directions of the sensor edge, enabling the extraction of the active sensor thickness and mechanical tilt via pixel intensity profiles. Lateral scans across pixel boundaries revealed a periodicity of the spatial modulation of mean cluster size compatible with the pixel pitch of the matrix. Taking the cluster size as the main figure of merit, the performance of the sensor was evaluated at different thresholds and multiple bias voltages in order to assess the variation in the Coulomb cone and collection dynamic. The measurements are supported by Allpix Squared Monte Carlo framework, demonstrating good consistency between the simulated and the real domain.

Abstract

High-energy physics experiments currently use Low Gain Avalanche Diodes (LGADs) as part of their time-of-flight layers to track particles, thanks to their unique temporal resolution and radiation hardness. With increasing deposited charge, the gain was observed to decrease. This gain suppression effect originates from the electrostatic field screening produced by the avalanche multiplication charge. This work investigates the resilience of the LGADs to the gain suppression by characterizing a set of detectors with different gain layer designs and thicknesses, using Transient Current Techniques.

Abstract

Mobility (μ), lifetime (τ), and mobility–lifetime product (μτ) are key metrics for semiconductor radiation detectors. Highly concentrated trapping centers or defects can distort the internal electric-field distribution, producing reduced-amplitude slow-rising charge-sensitive preamplifier pulses that degrade carrier-transit and charge-collection analyses. Although slow-rising-pulse rejection is commonly used to sharpen pulse-amplitude peaks and suppress low-amplitude tails, this work extends its use to charge-carrier transport characterization. A CdZnTeSe detector [1, 2] was characterized at room temperature under electron- and hole-transit-dominant conditions using ^{241}Am alpha irradiation. Pulse-shape analysis rejected slow-rising pulses for key metrics extraction. In electron-transit-dominant measurements, the fast-rising pulse events preserved the bias-dependent peak-centroid trend and yielded $(\mu\tau)_e$ = 5.7×10^{-4} cm²/V, μ_e = 576 cm²/V·s, and τ_e = 1.0 μs, consistent with reported values [3,4]. For hole-transit-dominant measurements, all-pulse events obscured the pulse-amplitude peak and hindered Hecht fitting. After rejection, we obtained $(\mu\tau)_h$ = 2.1×10^{-4} cm²/V, τ_h = 0.7 μs, comparable to reported values [5], with μ_h = 318 cm²/V·s. Using the rise-time peak as the representative transit time, both all-pulse and fast-rising-pulse events yielded similar μh values. However, when the median rise time of all-pulse events was used instead, drift velocity did not show a clear linear dependence on electric field, whereas fast-rising-pulse events retained linearity. This reflects the need for careful consideration of slow-rising components and the transit-time definition. These results show that slow-rising-pulse rejection enables reliable transport characterization beyond spectral improvement.

The Sensor, Packaging and INtegration (SPIN) group at Fondazione Bruno Kessler (FBK): capabilities, facilities and expertise (#2415)

David Novel, Tiziano Facchinelli, Evgeny Demenev, Alessandro Lega, Pietro Tosato, Sara Ferrari

Fondazione Bruno Kessler, Trento, Italy

Abstract

This contribution presents the capabilities, infrastructure, and technical expertise of the Sensor, Packaging and Integration (SPIN) group at Fondazione Bruno Kessler (FBK). The SPIN unit has established experience in the miniaturisation and integration of electronic systems for radiation detectors, with demonstrated results in space instrumentation (e.g. THESEUS for ESA), high-energy physics (e.g. R&D for ALICE3), and medical applications (e.g. the BOA project within INFN). These domains impose stringent constraints on material budget, geometrical footprint, and signal integrity, motivating the development of dedicated integration strategies. The group core expertise lies in the co-design of sensors and front-end electronics for operation in highly constrained volumes, where standard packaging solutions are not applicable. This includes the optimisation of interconnect technologies (wire bonding, TAB, flip-chip), layout strategies and the implementation of low-noise architectures. Emphasis is placed on preserving signal integrity in high-density environments typical of modern detector systems. SPIN offers end-to-end capabilities covering system design, prototyping, assembly, and characterisation, supported by dedicated infrastructure for precision packaging and electrical testing. A key enabling technology is the use of flexible and hybrid electronics, allowing the development of low-mass, conformable interconnects and non-planar integration schemes. In particular, the group has developed dedicated processes for the fabrication and integration of ultra-thin Kapton-aluminium flexible circuits, optimised for low material budget and high mechanical compliance. These structures enable the realisation of fine-pitch routing on lightweight substrates, with controlled thickness and reduced radiation length, making them especially suitable for tracking detectors.

High-voltage stress test and thermal recovery of an amorphous-silicon-passivated planar HPGe detector (#2646)

LiHui Han[1,2], Yulan Li[1,2], Li He[1,2], Siyuan Yu[1,2], Xiuxia Li[1,3], Mingxin Yang[1,2], Yuanjing Li[1,2], Yang Tian[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Ministry of Education, Key Laboratory of Particle & Radiation Imaging (Tsinghua University), Beijing, China; [3] Greater Bay Area National Center of Technology Innovation, Guangzhou, China

Abstract

High-purity germanium (HPGe) detectors are widely used in low-background and rare-event measurements because of their excellent energy resolution and relatively high detection efficiency. Compared with a-Ge, sputtered a-Si provides a higher electron-injection barrier, which is attractive for planar detectors under high electric fields. However, the high-voltage (HV) stability of a-Si contacts and the recovery from HV-induced large leakage-current and resolution degradation remain insufficiently understood. The detector was fabricated using a planar p-type HPGe crystal (φ24 mm × 10 mm). A Li-diffused n+ contact was used as the high-voltage electrode, while the opposite face was coated with an a-Si layer deposited by magnetron sputtering. A central Al pad was formed on the a-Si layer by thermal evaporation and used as the signal readout electrode. I–V curves were measured with a picoammeter up to 2500 V, and 57Co spectra were acquired at 500–2000 V using a DSPEC-50 digital spectrometer. The stress test consisted of repeated biasing up to 2000 V, followed by 9 hours of room-temperature storage and 9 hours of thermal treatment with the crystal holder maintained below 70 degrees. After the high-voltage stress test, the leakage current at 1000 V increased to approximately 1.1 nA, more than two orders of magnitude higher than the initial level. After thermal treatment below 70 degrees, the leakage current at 1000 V decreased to less than 2 pA, close to the as-fabricated level. At 1000 V, the resolution broadened to 1.53 keV FWHM, suggesting larger noise and contact-related instability under a higher electric field. After thermal treatment, the resolution at 500 V recovered to 0.67 keV FWHM, comparable to the initial value. In the future, we will repeat stress-recovery cycles, and investigate the dependence on treatment temperature and duration. The possible underlying recovery mechanism related to the a-Si fermi level will also be studied.

Abstract

The COMET Experiment at J-PARC aims to search for the muon-to-electron conversion process with a sensitivity of 10−17. In COMET Phase-I, the muon beam monitor (MBM) will be installed downstream of the primary detector system for background suppression and precise beam control. Since the MBM directly measures the high-intensity muon beam, silicon carbide (SiC), one of the wide-bandgap semiconductors with higher radiation tolerance, is employed as the detector material. The SiC sensor was jointly developed by KEK and AIST, and a beam test performed at J-PARC MLF in 2024 showed successful muon detection and sufficient linearity for operation in the COMET Experiment. In addition, a radiation-tolerant ASIC currently under development at KEK is planned for the SiC detector readout. While the initial prototype MBM board utilised a two-layer polyimide PCB to minimise the material budget, it suffered from external noise and inter-channel crosstalk, obscuring low-amplitude beta-ray signals. To address this and optimise the final MBM board design, we developed a test board equipped with seven SiC detectors. This study showed that noise can be reduced by implementing appropriate noise mitigation techniques, such as a ground plane in a standard PCB structure, enabling stable waveform acquisition of low-amplitude beta-ray signals. In addition, inter-channel crosstalk was effectively suppressed to a negligible level by introducing low-pass filters on the bias supply lines close to each detector. Based on these findings, a prototype MBM board for the final system is currently being developed. This presentation also reports on its design and initial performance evaluation.

Abstract

Lead oxide (PbO) is a high-atomic-number photoconductor for direct-conversion X-ray imaging. This work compares PbO layers produced by three deposition regimes: conventional physical vapor deposition from molten PbO powder, oxygen ion-assisted PVD, and argon ion-assisted PVD. All layers were deposited on indium tin oxide

coated glass substrates with a polyimide blocking layer to reduce dark current and were characterized by scanning electron microscopy, Raman spectroscopy, profilometry, density measurements, and X-ray photoconductivity. Deposition without ion assistance produced low-density polycrystalline PbO with noticeable lag in the X-ray response after irradiation. Oxygen ion-assisted growth yielded dense amorphous PbO with essentially lag-free temporal response. In contrast, argon ion-assisted deposition preserved the polycrystalline structure while producing a more uniform layer with intermediate density and needle-like surface crystallites. X-ray photocurrent measurements showed that the argon-assisted films had an electron–hole pair creation energy, W±, of approximately 6 eV/ehp at 10 V/μm, close to the fundamental limit. Under 30 Hz modulated X-ray irradiation, these films showed stable photocurrent during exposure and rapid signal decay after irradiation stopped, indicating negligible lag.

Abstract

Short-wave infrared photodetectors based on colloidal quantum dots (QDs) have attracted substantial attention owing to their solution processability, tunable bandgaps, and natural compatibility with silicon-based readout integrated circuits. However, the performance of QDs photodetectors is fundamentally limited by the low intrinsic carrier mobility of colloidal QDs, which significantly hinders charge transport. In addition, conventional detector

architectures typically provide insufficient internal gain, thereby restricting detection sensitivity, particularly under weak infrared illumination. To address these challenges, we propose a hybrid avalanche photodetector that integrates a halogen-passivated PbS QDs absorption layer with a silicon multiplication region. After absorbing incident infrared photons in the QDs layer, photoexcited electrons are efficiently injected into the silicon multiplication region. The accelerated carriers then induce impact ionization, which enables strong avalanche multiplication and yields high internal gain for efficient carrier collection. Technology Computer-Aided Design (TCAD) simulations indicate that the proposed device delivers a responsivity of 29.5 A/W at a wavelength of 1550 nm, accompanied by fast rise and fall times of 305 ps and 306 ps, respectively. By integrating the spectral tunability of PbS QDs with the robust avalanche gain offered by mature silicon platforms, this architecture provides a highly promising, CMOS-compatible route toward next-generation, high-sensitivity infrared photodetection.

Characterization and Radiation Damage Mitigation of Silicon Photomultipliers for Low Earth Orbit Applications (#1902)

Shideh Davarpanah, On behalf of NUSES Collaboration

Université de Genève, Département de physique nucléaire et corpusculaire, Genève, Switzerland

Abstract
Silicon photomultipliers (SiPMs) are attractive photosensors for space applications because of their compact size, low cost, low operating voltage, high photon detection efficiency (PDE), and single-photon sensitivity. Their use in space applications, however, is limited by radiation-induced increases in dark count rate (DCR). This work presents the characterization and radiation tolerance study of FBK NUV-HD-MT SiPMs for the focal plane of the Terzina Cherenkov telescope onboard the NUSES mission, which will operate in a Sun-synchronous low Earth orbit (LEO) at an altitude of approximately 550 km. Devices with micro-cell sizes ranging from 25 to 50 μm were evaluated through a comprehensive characterization campaign comprising static (current-voltage), dynamic (noise and pulse-shape), and optical (photon detection efficiency) measurements to identify the sensor configuration best suited for this application. The 30 μm bare sensors were selected as the optimal solution, achieving a PDE greater than 50% at 400 nm, optical cross-talk below 2%, and a DCR below 60 kHz/mm^2 at 10 V overvoltage. The radiation environment was modeled using SPENVIS, and dose deposition in the focal plane was evaluated with Geant4

simulations. In parallel, radiation effects were investigated experimentally through two irradiation campaigns: a 50 MeV proton beam test and electron exposure using a Sr-90 source. Proton-induced damage produced a significant increase in leakage current and DCR, while electron-induced degradation was substantially smaller. Temperature-dependent measurements were used to extrapolate in-orbit performance and to evaluate recovery through thermal annealing. The results indicate that performing periodic annealing cycles at temperatures above 50°C can reduce the radiation-induced current by up to 40% after approximately 84 hours, helping preserve detector performance over the three-year mission.

Toward SiPM Single-Photon Detection Matrix using Ultrafast, Low Power RF Readout (#1939)

Rafik Belkacem[1], Dominique F. Yvon[1,4], David Baudin[2], Dominique Breton[3]

[1] CEA Saclay / Univ. Paris-Saclay, IRFU/DPhP, Gif sur Yvette, France; [2] CEA Saclay / Univ. Paris-Saclay, IRFU/DEDIP, Gif sur Yvette, France; [3] CNRS-IN2P3/ Univ. Paris-Saclay, IJCLab, Orsay, France; [4] UMR BioMaps/ Univ. Paris-Saclay, Orsay, France

Abstract

To enable the readout of fast signals from SiPM arrays, we have developed a SiPM chip readout based on a compact, low-power radio-frequency preamplifier, thus avoiding the use of ASICs. On a 16 mm² SiPM operating in single photoelectron mode, we measure a rise time of 450 ps and a timing resolution (SPTR) of 84 ps (FWHM), while amplifying the fast component of the SiPM pulses. Furthermore, the active output impedance of the preamplifier is on the order of kΩ, allowing these chips to be mounted along a transmission line without significantly affecting signal propagation. This enables the implementation of dense SiPM lines or arrays, reducing the number of digitization channels required for readout. Finally, an optimized passive pole-zero compensation network, placed at the ends of the line, suppresses the slow component of the SiPM pulses and achieves critical damping of the fast pulse shapes. Thus, pulse pile-up, expected during multiplexing of SiPM photodetectors, can be controlled even at high counting rates. We are currently working on the assembly of such SiPM arrays. We measured a

Coincidence Time Resolution of 69 ps (FWHM) using a 9 mm^3 LYSO crystal + SiPM spectrometers with our readout electronics.

FPGA-Based Real-Time SiPM Emulator with Sub-Nanosecond Temporal Quantization (#1987)

Andrea Abba[1], Stefano Carsi[1], Francesco Caponio[1], Edoardo Proserpio[1,2], Valentina Arosio[1]

[1] Nuclear Instruments SRL, Lambrugo, Italy; [2] Università dell'Insubria, Como, Italy

Abstract

This work presents a real-time FPGA-based Silicon Photomultiplier (SiPM) detector emulator capable of reproducing physically accurate detector waveforms at 16-bit resolution and 2.5 GS/s analog output rate. The proposed architecture combines microscopic event simulation with a temporally quantized event-streaming model, enabling real-time waveform synthesis directly inside FPGA logic while drastically reducing bandwidth requirements compared to traditional waveform streaming approaches. The emulator separates event generation from signal shaping: software layers generate timestamped photon-hit sequences derived either from analytical distributions, Geant4 simulations, or SimSiPM microscopic detector models, while the FPGA reconstructs the analog waveform through parallel Infinite Impulse Response (IIR) filter banks implementing the SiPM transfer function; a look-ahead recursive transformation enables II = 1 operation across all banks at 156.25 MHz, consuming approximately 235 DSP48E2 slices. A multi-phase temporal quantization architecture provides 0.8 ns effective timing precision using a 156.25 MHz fabric clock and eight temporal sub-phases. Experimental validation demonstrates excellent agreement between hardware-generated waveforms and analytical as well as SimSiPM-generated references, including pile-up scenarios with overlapping scintillation events reproduced through linear superposition. The prototype operates with an end-to-end latency of approximately 83 ns.

Abstract

This paper presents the single-cell design and verification of a digital SiPM building block with an integrated temperature-compensation architecture that eliminates external sensors by exploiting SPAD output-amplitude tracking as an intrinsic thermal indicator. A low-power SPAD with a P+/N-well junction and P-well guard ring was fabricated in a 180 nm CMOS process, exhibiting a 10.3 V breakdown voltage, while the digital-cell employs a high-speed comparator to suppress pulse-width variation and premature edge breakdown. The extracted amplitude trend drives an integrated PMIC in a closed loop to dynamically adjust the SPAD bias, maintaining a constant overvoltage and providing instantaneous compensation for thermal drifts.

Graphene Photodetectors for Vacuum-UV Through Visible Wavelengths (#3124)

Alec Lindman[1], Marcos Turqueti[1], Lisa Schlueter[1], Gabriela R. Araujo[2]

[1] Lawrence Berkeley National Laboratory, Berkeley, USA; [2] University of Zurich, Zurich, Switzerland

This work was supported by the U.S. Department of Energy through the Laboratory Directed Research and Development program.

Abstract

Many experiments rely on measuring vacuum-ultraviolet light, which is emitted in situations as diverse as scintillation in cryogenic liquid noble gases (126.8 nm in argon) and laser spectroscopy of atomic hydrogen isotopes (121.6 nm). Graphene-monolayer photodetectors offer several attractive traits: they are naturally thin, sensitive to a broad range of wavelengths, relatively simple to fabricate (including with integrated readout circuitry with the same process), and can be made on flexible substrates. We present measurements with visible and UV light down to 115 nm, including at low intensity and with fast pulses, of graphene field-effect transistors (GFETs) of various sizes up to 2 mm square fabricated on silicon. These detectors show promise for experiments from neutrinoless double beta decay searches to absolute neutrino mass measurements, as well as dark-matter searches or other VUV-detection applications.

Work supported by the U.S. Department of Energy, under contract number DE-AC02-76SF00515.

Abstract

Linac Coherent Light Source (LCLS) at SLAC National Laboratory has been going through a major upgrade, called LCLS-II, where the repetition rates are increasing from 120Hz to almost a MegaHertz. Custom ASICs that support x-ray data measurements at these rates are in development for both full frame and sparse data readout. For these

ASIC designs we are departing from conventional internal PLL architectures, and instead implementing a 6.25 Gbps serializer with high-speed current-mode logic (CML) receivers (for clock) and transmitters (for data). This approach simplifies the whole chip design, reduces the power consumption and minimizes the noise sensitivity between the high-speed data path and the low-noise front-end blocks. This paper presents detailed performance measurements in a prototype ASIC, followed by the description of their circuit design and implementation.

Performance Evaluation of Differential Amplifiers for Fast Scintillating Fiber Readout in Proton Therapy (#1449)

Bayram Deniz[1,2], Ali Eksim[1,2]

[1] TUBITAK BILGEM, KOCAELI, Turkey; [2] Gebze Technical University, KOCAELI, Turkey

The authors thank the TUBITAK BILGEM Embedded Systems and Digital Design Team and the NOVO Project Team for their technical support and collaboration throughout this work.

Abstract

Real time range verification in proton therapy requires analog front end electronics that can process fast, low amplitude signals from scintillating fibers with sub nanosecond precision. This work compares two COTS differential amplifiers (ADA4930 vs. ADA4938) for the NOVO project's detector. Using actual scintillator derived PWL pulses (0.3 V peak, 18 ns rise time) and a 5th order 250 MHz Butterworth filter, we show that small signal bandwidth governs transient performance. The ADA4930 achieved 660 V/µs pre filter and 350.56 V/µs post filter slew rate, versus 550 and 289.44 V/µs for the ADA4938. Noise analysis reveals the ADA4930 is "resistor noise limited" (61.4% passive resistors), while the ADA4938 is "IC noise limited" (71.6% internal noise). The ADA4930 yields SNR = 65 dB and ENOB = 10.6 bits, outperforming the ADA4938 (62 dB, 10.0 bits). The ADA4930 is therefore the optimal driver for maximizing slope to noise ratio and minimizing timing jitter.

Design of the new Matterhorn detector for the 4th generation synchrotrons (#1694)

Davide Mezza, Michele Anastasi, Anna Bergamaschi, Martin Brueckner, Roberto Dinapoli, Maria Carulla, Simon Ebner, Simone Emiliani, Khalil Ferjaoui, Viveka Gautam, Dominic Greiffenberg, Erik Froejdh, Shqipe Hasanaj, Viktoria Hinger, Markus Huerst, Vadym Kedych, Thomas King, Shuqi Li, Carlos Lopez-Cuenca, Leonid Lunin, Alice Mazzoleni, Scharon Moses, Kostantinos Moustakas, Aldo Mozzanica, Jonathan Mulvey, Martin Mueller, Christian Ruder, Bernd Schmitt, Saverio Silletta, Dhanya Thattil, Xiangyu Xie, Jiaguo Zhang

Paul Scherrer Institute (PSI), SLS Detector Group, Villigen, Switzerland

Abstract

The new fourth-generation storage rings (diffraction-limited storage rings), such as those at MAX IV Laboratory, ESRF EBS, and Swiss Light Source 2.0, will provide significantly higher brilliance than third-generation sources, resulting in a much larger photon flux at the pixel level. This increased flux will exceed the count-rate capabilities of many single-photon counting detectors currently in use, making them unsuitable for future experiments at these facilities. Matterhorn is a 2-D hybrid pixel detector developed by the PSD detector group at the Paul Scherrer Institute for operation at SLS 2.0. Its main objective is to extend the count rate capability to a target of 20 Mcounts/pixel/s using multi-threshold circuitry implemented in each pixel. The Matterhorn ASIC features a 256 × 256 pixel matrix with 75 µm pitch and is implemented in UMC 110 nm technology. Each pixel includes a charge-sensitive amplifier and a shaper connected to four comparators with independently adjustable thresholds. Setting thresholds above the photon energy enables an extension of the effective count-rate capability. Each comparator is connected to an independently gateable 16-bit counter. The target frame rate for reading out one 16-bit counter per pixel is 10 kHz. To support this rate, the ASIC periphery includes four serial links operating in double data rate mode at up to 3.125 GHz, driven by a 1.5625 GHz clock generated by an on-chip PLL. A fully synthesized digital periphery provides flexible ASIC configuration. Since January 2026, the final ASIC, which is fully functional, has been under test to evaluate its performance. This contribution focuses primarily on the ASIC design and detector architecture, and reports the main performance parameters measured so far, while a detailed discussion of the full characterization results will be presented in a separate contribution.

NSS-01-095

A Low-Latency 28-nm CMOS ASIC for Superconducting Quantum Readout (#1815)

Yunzhuo Zhang[1], Cheng Guo[2], Xinzhe Wang[2], Wenyi Peng[2], Futian Liang[2]

[1] University of Science and Technology of China, school of physical science, hefei, China; [2] University of Science and Technology of China, Hefei National Laboratory, hefei, China

Abstract

As the scale of the superconducting quantum control system continues to expand, traditional field-programmable gate array architectures face bottlenecks such as high energy consumption, low scalability, and severe signal attenuation. This paper proposes a highly integrated, low-latency digital front-end architecture fabricated in a 28-nm CMOS process to meet dynamic feedback requirements and optimize power, performance,and area. The front-end includes an arbitrary waveform generator and a data acquisition module, independently managed by a microcontroller. At the transmitter, a digital-to-analog converter
is used to output analog signals, with a measured spurious free dynamic range of 52 dB. At the receiver, a low-latency analog-to-digital converter captures analog signals, which the data acquisition module demodulates and ultimately uploads via a low-voltage differential signaling interface. The total hardware latency is restricted to approximately 100 ns. Under full-load testing conditions—including continuous waveform generation,concurrent demodulation of 16 qubits, and state feedback—the total digital power consumption is limited to 539 mW(33.7 mW/qubit). This design achieves extremely low latency and excellent energy efficiency, satisfying the real-time control demands of scalable fault-tolerant quantum computers.

Radiation Effects on COTS On-Board Computer and Boot/Data-Storage Media Configurations for Super-Low-Earth-Orbit Optical Satellites

(#1893)

Jongdae Sohn[1,2], Hojin Lee[1,2], Hyosang Yoon[3]

[1] Korea Astronomy and Space Science Institute, Division of Space Exploration, Daejeon, South Korea; [2] University of Science and Technology, Department of Astronomy and Space Science, Daejeon, South Korea; [3] Korea Advanced Institute of Science and Technology, Department of Aerospace Engineering, Daejeon, South Korea

Abstract

Super-low-Earth-orbit (SLEO) optical satellites require compact on-board computing and data-storage electronics, but commercial off-the-shelf (COTS) on-board computers (OBCs) and boot/data-storage media must retain boot, communication, and read/write functions under the mission radiation environment. This paper reports a configuration-level radiation screening of COTS OBC candidates for a 300 km-class, 2-year SLEO optical satellite. A SPENVIS/SHIELDOSE-2 dose assessment gave a total ionizing dose of 14.345 krad(Si) for the design case; therefore, a conservative 30 krad(Si) TID screening target was selected by applying a margin factor of approximately 2. The screening campaign included Arduino and Raspberry Pi family boards, and the detailed design interpretation focused on Raspberry Pi Compute Module 4 (CM4) with input/output board and nonvolatile boot/data-storage media, including Secure Digital (SD) cards, embedded MultiMediaCard (eMMC), solid-state drives (SSDs), and hard disk drives (HDDs). Devices were irradiated with cobalt-60 gamma rays, 10 MeV electrons, and 100 MeV protons, and were evaluated by boot status, communication, supply-current and voltage behavior, read/write operation, and recovery after irradiation. The results indicate that CM4-based configurations were more suitable than the other screened modules for the SLEO OBC candidate. Among storage options, eMMC showed the most favorable radiation and operational suitability, SSDs were identified as a practical secondary storage option after configuration-level verification, and HDDs were not recommended for spacecraft on-board use although some configurations survived to approximately 30 krad(Si), because rotating mechanical parts can affect spacecraft operation. These results support qualifying the exact OBC and boot/data-storage configuration, rather than only the processor board, for COTS-based SLEO on-board computing and storage electronics.

Abstract

The integration of Silicon Photomultipliers (SiPMs) into high-resolution radiation detection systems has become increasingly relevant in the search for novel methodologies in precision energy measurement. This fact implies the need of front-end electronics capable of properly working with these sensors, whose parasitics change among different parts. In the signal processing chain, the initial stage must offer maximal linearity to preserve signal integrity throughout the subsequent architectures. A low-noise goal is also important in order to optimize energy resolution since first stage is critical in noise budget. Consequently, a specialized preamplifier design is presented in this paper in order to address these requirements. The primary design challenge involves achieving a very good linearity through high internal loop gain without compromising system stability. To ensure a controlled frequency response, the circuit employs a Miller compensation scheme whose dominant pole is inside the circuit. Constructing a robust stability topology, the architecture can handle diverse parasitic components in its input due to the use of different SiPM devices. In a first amplification stage, a key innovative structure has been developed as a translinear wideband inner gain stage. Furthermore, to ensure an extended dynamic range which allows working in both photon counting and high amplitude signal conditions without design reconfiguration, a digitally controlled attenuator system is integrated at the output of the first stage. The attenuator uses a R-2R ladder architecture implemented with MOSFET technology, allowing for direct gain adjustments and accurate calibration through external control logic.

SPAGHETTI : An original instrument for the continuous gamma-ray based monitoring of hydrothermal volcanoes (#2092)

Hervé Chanal, Cyrille Achard, Jonathan Bonnard, Vincent Breton, Emmanuel Busato, Christophe Insa, Jonathan Lao, Gilles Magaud, Hervé Croizet, Magali Magne, Valentin Niess, David Picard, Valentin Rabant, Luca Terray

Université Clermont Auvergne, CNRS/IN2P3, LPCA, Clermont-Ferrand, France

Abstract

Hydrothermal volcanic systems are associated with major hazards such as magmatic/phreatic eruptions and toxic gaz emissions.
Monitoring fluid circulation within these systems is a key scientific challenge.
The SPAGHETTI project (Spectral Panoptic Analyzers of Gamma rays in Hydrothermal Environments for Transport Time Inference) aims to develop
an original instrument dedicated to the continuous and high-frequency monitoring of radon using gamma-ray spectroscopy.
The instrument relies on NaI scintillation detectors coupled to a specific signal processing electronics.
The whole system is designed to withstand high temperatures, extreme humidity, and acidic corrosion.
This contribution focuses on the FPGA-based digital signal processing chain implemented on a low-cost ADC-SoC platform.
Real-time triggering, digital filtering, and amplitude extraction are performed directly in programmable logic.
First tests aiming to demonstrate the capability of the system to continuously
acquire and process scintillation signals in conditions representative of volcanic hydrothermal environments will be presented.

Evaluating AMD's Versal Architecture for Tapped Delay Line Time-to-Digital Converters. (#2179)

Julien Rossignol, Sun Il Kwon

University of California, Davis, Biomedical engineering, Davis, USA

This work was supported by the National Institutes of Health under grant R01 EB033536.

Abstract

Performances of tapped delay line (TDL) time-to-digital converters (TDCs) in FPGAs are strongly linked to the FPGA fabrication process, with newer fabrication processes usually yielding smaller propagation delays, thus improving the resolution and precision of the fine measurement. This study evaluates TDLs designed inside the Versal architecture, AMD's newest architecture that uses a 7 nm fabrication process. Since the Versal architecture's new configurable logic blocks (CLB) allow for multiple propagation paths through them, three different implementations of a TDL were evaluated. Code density and single-shot precision measurements were performed on five pairs of channels for each implementation. The lowest quantization error, 4.47 ps, was obtained using a mix of the outputs of the carry propagation circuit and the look-up tables (LUTs) of the CLB, while the best single-shot precision, 7.51 ps, was obtained by using only the output of the LUTs. Because of the change in the CLB design, TDL TDCs perform significantly worse than in AMD's previous architecture.

Abstract

The Multi-Voltage Threshold (MVT) method is widely employed in particle detection. However, limited by discrete hardware architectures, existing FPGA-based digitization systems struggle to fully exploit the fundamental timing potential of photodetectors. To investigate these performance limits, we systematically evaluate the ultimate timing performance of a detection chain comprising a CMOS SiPM and an in-house-developed MVT ASIC. This ASIC features picosecond time quantization and a wide dynamic range. Experimental results show that, under excitation from a synchronized picosecond laser source, the MVT ASIC achieves an intrinsic electronic time resolution of 16.94 ps (FWHM) and a coincidence time resolution (CTR) of 16.58 ps (FWHM). Benchmarking against a high-performance digital oscilloscope demonstrates that the timing precision of the MVT ASIC closely approaches that of laboratory-grade instrumentation (11.74 ps). This work validates the potential of the MVT ASIC for time-of-flight (TOF) measurement systems and establishes a promising technical foundation for ultra-high-resolution TOF detection.

This work was carried out in the framework of the PiHex project, CUP F53D23001490006 - PRIN 2022, funded by NextGenerationEU - M4, C2, 1.1.

Abstract

A demonstrator chip integrating a matrix of 32 x 8 readout channels for hybrid pixel detectors has been designed and tested in the framework of the PiHEX project, funded by the Italian Ministry of University and Research. The front-end channels include a low-noise charge sensitive amplifier with detector leakage compensation, an asynchronous, differential comparator, and a 5-bit threshold tuning DAC. A Time-over-Threshold counter is integrated for signal digitization. The front-end channels have been developed in a 28 nm CMOS technology and feature an overall area of 25 um x 100 um with a current consumption close to 4.2 uA. Full details on the design and characterization of the prototype chip will be reported in the conference paper.

A 5.12-GS/s Time-Interleaved VCO-Based ADC With Digital Calibration for High-Speed Detector Waveform Digitization (#2436)

Chenxi Chen, Yuchen Hu, Simeng Chen, Xueye Hu, Jinghong Wang

University of Science and Technology of China, Hefei, China

Abstract

This paper presents a 5.12-GS/s time-interleaved voltage-controlled-oscillator-based analog-to-digital converter (VCO-based ADC) for high-speed detector waveform digitization in nuclear science and high-energy physics experiments. The proposed ADC employs an 8-channel time-interleaved architecture, where each sub-channel operates at 640 MS/s, resulting in an aggregate sampling rate of 5.12 GS/s. VCO-based quantization is adopted to exploit time-domain signal processing and inherent first-order noise shaping. Each sub-channel integrates a high-linearity bootstrapped sampling switch, a 15-stage ring-VCO quantizer, multi-phase sampling flip-flops, and an asynchronous coarse counter to realize hybrid coarse-fine quantization. To address the major performance limitations of VCO-based and time-interleaved ADCs, a digital calibration scheme is introduced to compensate for the VCO voltage-to-frequency nonlinearity and inter-channel timing skew. The ADC is implemented in a 55-nm CMOS process. Post-layout simulation results show that, at an aggregate sampling rate of 5.12 GS/s with a 2.4-GHz input signal, the ADC achieves an SNDR of 37.5 dB and an effective number of bits of 5.94 bits after calibration. The simulated power consumption is 75 mW from a 1.2-V supply, corresponding to a Walden figure-of-merit of 239 fJ/conversion-step. Full-chip performance measurement is currently underway, and the measured results will be reported at the conference. These results demonstrate the potential of the proposed digitally calibrated TI VCO-based ADC for compact, high-speed detector readout systems.

Development of an FPGA-based Hardware Data Injector for High-Energy Experiments (#2845)

Marcel M. Boonen, Davide Cieri, Oliver Kortner, Sandra Kortner

Max Planck for Physics, Munich, Germany

Abstract

Most high-energy experiments at CERN are upgrading their trigger systems for the upcoming high-luminosity era of the LHC. At the same time, development started on the trigger systems of future collider experiments. To fully validate those new systems and developments, it is necessary to test both the algorithms and the underlying interfaces under consideration in a faithful manner. For the former, simulations are used, and for the latter small-scale hardware test stands are typically used. This project proposes the usage of an FPGA-based hardware data injector, which could replicate at the same time the expected fast trigger data rate and transmission protocols. By storing Monte-Carlo simulated data in a DDR4 memory and subsequently transmitting it continuously to a trigger board under test using Gigabit Transceivers, the emulator can mimic the expected low latency data flow.

MU-STAR-mini: A 5-GS/s Prototype Sampling Array for High-Resolution Multi-Channel Streaming Readout (#3057)

Luca Macchiarulo, Isar Mostafanezhad, Eyan Forsythe, Justine Horikawa, Kahiwa Hoe, Greg Uehara, Joseph Cardenas, Christopher Chock

Nalu Scientific, LLC, Honolulu, USA

This work was partially funded under U.S. DOE DE-SC0025827 award.

Abstract

In this article we describe the design and prototyping of the MUlti-channel Streaming Autonomous Readout chip (MU-STAR-mini) to explore the design limits of fast (5 Gsps) sampling array architectures for high voltage resolution, and probe the hypothesis that such architecture can be competitive in resolution and advantageous in terms of power, density and data reduction when compared with traditional ADC architectures for impulsive applications as they are often found in particle physics. We will describe the design and fabrication of the sampling array architecture, the design and fabrication of its test board, and its initial testing.

Implementation of FPGA-Based Time-to-Digital Converters with Zero Measurement Dead Time (#1024)

Xinren Qi, Yonggang Wang

University of Science and Technology of China, Department of Modern Physics, Hefei, China

Abstract

Field programmable gate array (FPGA)-based time-to-digital converter (TDC) has played a very important role in facilities of high-energy physics and scientific instrumentation. Some applications even require TDCs without measurement dead time. In this paper, normal tapped delay line (TDL) based TDC structure is modified towards the realization of zero dead time without losing any TDC original performance. The major challenge in this situation is that there will be more than one signal transition edge in the latched TDL status, therefore, a robust multi-signal transition edge detection circuit module and calibration module are crucial. On a Xilinx UltraScale FPGA, the latched TDL status is first decomposed into 32 divisions, which execute the transition edge picking up parallel before they are combined together to give out all the edges. Since there is only one calibration table in the system, all the edges have to be calibrated sequentially through a specially designed data queue. For performance evaluation, the TDC prototype is implemented on the FPGA with a system clock frequency of 700 MHz. The TDC resolutions for the rising and falling edges are measured as 2.44 ps and 2.31 ps respectively, meanwhile the root-mean-square (RMS) time-interval measurement precisions are measured in the range of 3.5 to 6.5 ps. Applying two trigger signals with 500 ps separation into the TDC repeatedly, all the edges are captured and correctly measured, which demonstrates the capability of zero measurement dead time of the design.

Abstract

The Circular Electron Positron Collider (CEPC) is a large-scale international high-energy physics facility with the Higgs boson as its primary scientific goal. Three operation modes are foreseen: Higgs, Z, and W+W-. The CEPC Trigger and Data Acquisition (TDAQ) system faces a fundamental challenge: extracting rare physics events from an extremely high background rate. For example, in the Higgs mode, simulation results indicate that the target physics event rate is approximately 0.5 kHz, while the bunch crossing rate reaches 1.34 MHz. To cope with this challenge, the required Level-1 (L1) trigger rate for the Higgs mode is about 20 kHz.This extremely low signal-to-background ratio demands a trigger system capable of making efficient and real-time trigger decisions to achieve high-purity event selection while maintaining high efficiency for rare physics signals.To facilitate research and verification of the trigger system design, this talk presents a general-purpose Advanced Telecommunications Computing Architecture (ATCA) processing unit for the CEPC TDAQ system. The unit features an AMD Virtex UltraScale+ field-programmable gate array (FPGA) as its computing core, providing high-density parallel processing. High-speed data transmission is achieved via the FPGA's Gigabit Transceiver (GT) and optical transceivers, offering standardized interfaces for electronic subsystems. The design incorporates 11 Quad Small Form-factor Pluggable (QSFP) modules providing 44 high-speed lanes up to 25 Gbps each, 16 GB of Double Data Rate (DDR) memory for hundreds of milliseconds of buffering, and an Intelligent Platform Management Controller (IPMC) + K26 system-on-module (SOM) for intelligent management. Developed as a flexible testbed, this unit enables the implementation and evaluation of various trigger algorithms and architectures. The test results of related trigger functionalities and performance will be presented in the talk at the conference.

Design of the Ultra-Low-Power Readout Electronics for the Large Area ^{3}He Tube Array Detector at China Spallation Neutron Source (#1266)

Weigang Yin[1,2], Yanlin Lai[1,2], Hongbin Liu[1,2], Qinglei Xiu[1,2], Yubin Zhao[1,2]

[1] Institute of High Energy Physics, Chinese Academy of Sciences, Beijing, China; [2] Spallation Neutron Source Science Center, Dongguan, China

Abstract

The China Spallation Neutron Source (CSNS) is currently upgrading to CSNS-II, increasing the proton beam power to 500 kW and constructing several new neutron spectrometers. The CSNS-II upgrade poses significant challenges for detector and electronics systems, including higher counting rate, improved position resolution requirement, and vacuum operating environment. The large-area ^{3}He tube array detector has been adopted as the major neutron detector owing to the high detection efficiency, the excellent neutron/gamma discrimination, and the ability to construct the detector with large area coverage. In this paper, we present an ultra-low-power front-end readout electronics designed for ^{3}He tube detectors in CSNS-II spectrometers. The circuit design, FPGA algorithms, and laboratory test results of the electronics will be discussed. Experimental results demonstrate that the new electronics system can achieve a single-tube counting rate of 100K/s while maintaining a position resolution about 6 mm. Test also confirmed the system's capability to operate under vacuum conditions. These results meet the requirements for neutron signal readout in CSNS-II spectrometers.

NSS-01-125

A modular, self-triggered firmware for the FPGA-based readout of electromagnetic calorimeters at the INSIGHT@ELSA experiment (#1294)

Benedikt Otto, On behalf of the INSIGHT collaboration

Bonn University, Helmholtz-Institut für Strahlen- und Kernphysik, Bonn, Germany

Abstract

This paper presents a modular, per-channel self-triggered firmware architecture for the FPGA-based readout of electromagnetic calorimeters at the INSIGHT experiment. The firmware integrates a compact deconvolution stage to compensate preamplifier trailing-edge ringing, a configurable, pipelined feature extraction chain (baseline estimation, peak-based trigger with interpolation, pileup detection), and a lightweight network module. The implementation uses a decomposition of the deconvolution kernel to reduce resource usage. Despite the computational demands, the implementation of the deconvolution is resource-efficient and leaves headroom for further extensions. A Python-based simulation framework guided the selection and tuning of algorithms and numerical parameters. Test-beam measurements with a detector module showed an effective ringing suppression

without affecting the pulse amplitude and timing; cooling the detector to the nominal operating temperature in upcoming runs is expected to further reduce residual artifacts. The resulting firmware framework provides a base for both electromagnetic calorimeters, the Crystal Barrel and the PANDA forward endcap calorimeter, in the INSIGHT experiment and will reduce maintenance effort.

Abstract

The Polarimetry Focusing Array (PFA) onboard the planned enhanced X-ray Timing and Polarimetry (eXTP) observatory comprises three identical X-ray imaging telescopes, providing X-ray polarimetry in the 2–8 keV energy range with high spatial, spectral, and temporal resolution. To meet these requirements, each detector unit integrates a radiation sensor with a dedicated Application-Specific Integrated Circuit (ASIC) for precise charge extraction and digitization of individual X-ray events.

This paper presents a readout ASIC designed for this application. The proposed ASIC features a self-triggering mechanism that enables event-driven readout with dynamically configurable windows. To satisfy stringent performance requirements, a two-stage analog readout architecture is adopted. Although the target system employs a 352 × 304 pixel array, a prototype ASIC with a 70 × 60 pixel matrix and a pitch of 50 μm was fabricated in a 180-nm CMOS process to validate the design.

Measurement results demonstrate an Equivalent Noise Charge (ENC) below 40 e^- rms. With a 12.5 MHz readout clock, the dead time for a typical event involving approximately 1000 pixels is maintained below 100 μs. These results verify the feasibility of the proposed ASIC architecture for the eXTP PFA instrument.

Abstract

Cerium doped gadolinium aluminium gallium garnet (GAGG:Ce) is capable of detecting both photons and charged particles. Particle identification capabilities present GAGG:Ce as a useful detector in nuclear physics research, and in medical, industry, security and space applications. This work explores the feasibility of using trapezoidal filtering for pulse shape discrimination (PSD) to perform particle identification so that the pulse height analysis (PHA) mode in commercially available waveform digitizers can be used without developing custom PSD firmware. Waveforms recorded from proton and alpha scattering measurements were analyzed offline to optimize the trapezoidal filter parameters. Satisfactory pulse shape discrimination was achieved with a figure of merit of 0.68. Future work will incorporate the optimized parameters in the waveform digitizers for heavy-ion reaction experiments to improve particle identification in real time.

Abstract

The HIE-ISOLDE Timing Array for Reaction Studies (HISTARS) is being developed for the measurement of lifetimes of excited nuclear states produced in reactions at HIE-ISOLDE (CERN). It is based on fast particle and gamma scintillator detectors that will require a fast data acquisition system capable of handling more than 60 channels with good time and energy resolution. Digitizing the fast scintillator signals will allow for a flexible signal processing, while preserving the pulse time structure, and potentially enabling high-precision timing.

In this work we measure the intrinsic time resolution of several digitizer systems for data acquisition and processing of data stemming from fast scintillators, such as LaBr$_3$(Ce). A very promising high-performance candidate is the CAEN 2751 digitizer, providing 14-bit, 1 GS/s, 16 channels, and embedded FPGA processing for advanced waveform acquisition and digital pulse processing.

The DRS4 Evaluation Board uses the DRS4 switched-capacitor array chip developed at Paul Scherrer Institute with 4 input channels, sampling rates of 0.7 to 5 GS/s with 1024 sampling cells at 14-bit resolution. The CAEN DT5742B is a 16-channel switched-capacitor digitizer based on the same DRS4 chip, providing 14-bit resolution and up to 5 GS/s sampling rate.

The CAEN DT5751 is a desktop digitizer 4 channels, 10-bit resolution, and sampling rate of 1 GS/s per channel.

An in-house custom microcontroller-based data acquisition system, capable of analog pulse integration and timestamp assignment based on a bespoke time to amplitude converter (TAC), is also included in the DAQ systems comparison. These results will guide the choice of the data acquisition system for the HISTARS project and determine its baseline contribution to the timing capabilities of the array.

Feasibility Study of Analog Pulse Processing ASIC for SDD Array in High Count Rate XRF (#2211)

Yuji Okubo[1], Daisuke Matsunaga[1], Carlo E. Fiorini[2,3], Giacomo Borghi[2,3]

[1] HORIBA, Ltd., Advanced R&D Center, Kyoto, Japan; [2] Politecnico di Milano, Dipartimento di Elettronica, Informazione e Bioingegneria, Milan, Italy; [3] INFN, Sezione di Milano, Milan, Italy

Abstract

Silicon Drift Detectors (SDDs) are the most widely used sensors for energy dispersive X-ray detection in the energy range from a few hundred eV to some tens of keV. When connected to a state-of-the-art CMOS preamplifier, they provide high energy resolution at short peaking times, allowing for high count rates. In high-count-rate X-ray fluorescence (XRF) measurements, SDD arrays are also considered; however, using conventional Digital Pulse Processors (DPPs) requires a large number of ADCs and FPGAs, leading to an increase in overall system size. To keep the total system compact, this study proposes an approach using the analog pulse processing ASIC "SCARLET" and investigates its feasibility. Using an actual XRF setup, a single SDD signal was input into the ASIC as an initial evaluation of its fundamental throughput performance and energy spectrum at an input count rate of up to 1.8 Mcps. The results show that with a 400 ns shaping pulse width, the ASIC could potentially achieve faster throughput compared to a conventional DPP with an equivalent filter length. However, with a 200 ns pulse width, the throughput decreased, and incorrect energy measurements were observed, such as the appearance of an unexpected peak on the lower energy side. This indicates that there are remaining issues in the peak detection logic within the ASIC. This study provides fundamental insights into the effectiveness of the analog ASIC for high-count-rate XRF measurements and highlights areas for future improvement.

Abstract

Timepix4 represents a significant advancement in the Timepix family of hybrid active pixel detectors, particularly attractive due to its fine time resolution (195 ps) and high supported hit rates (up to 5 GHz/mm2). To address performance challenges presented by these new features, an upgrade has been implemented for the Track Lab software package, which has become a standard tool for data collection and analysis of many Timepix-based systems. Above all, the presented upgrade adds support for a 40 Gb/s PCI-express readout interface, capable of reaching hit rates of 300–400 MHz. To facilitate efficient analysis of such data volumes, the presented work implements a number of optimizations, including memory-level bit packing, deduplication and GPU offload for hit clustering, a required step for most event-based analysis algorithms. This work will present details of these improvements, characterize Track Lab's response under heavy load and present results of a performance benchmark. The upgraded software is expected to find plentiful applications in high-intensity X-ray imaging, γ-imaging and the forthcoming high-luminosity campaign at the Large Hadron Collider.

Abstract

This paper presents a scalable and high-throughput data acquisition (DAQ) architecture developed for real-time proton beam monitoring applications in advanced proton therapy systems. The proposed system is designed to support detector-based tracking of proton energy deposition, enabling continuous monitoring of beam delivery and allowing treatment parameters to be adjusted dynamically during operation. By providing precise localization of proton energy release within the target region, the system contributes to improved dose accuracy while minimizing radiation exposure to surrounding healthy tissue. The DAQ architecture integrates high-speed digitization, synchronized timing distribution, and efficient event aggregation within a modular rack-based platform optimized for detector readout applications. The system consists of eight digitizer boards supporting 64 analog input channels corresponding to 32 detector elements. Differential signal readout is employed to improve signal integrity and reduce noise susceptibility during acquisition. A dedicated Data Collection Board equipped with 40 Gbps QSFP+ communication links aggregates and transfers acquired event data to a host DAQ server with high bandwidth and low latency. System-wide synchronization is maintained through a centralized Clock Distribution Board, while an OpenVPX-compliant Power Supply Board ensures reliable operation of all modules. The proposed architecture provides a compact, scalable, and synchronized solution for real-time proton therapy monitoring and high-performance medical imaging applications.

A Modular High-Bandwidth DAQ System for the Medipix4 ASIC Based on FPGA Ethernet Readout (#2665)

Nicolò Vladi Biesuz[1], Rafael Ballabriga[2], Jerome A. Alozy[2], Riccardo Bolzonella[2], Michael Campbell[2], Massimiliano Fiorini[3,1], Xavier Llopart Cudie[2]

[1] Istituto Nazionale di Fisica Nucleare (INFN), Ferrara Division, Ferrara, Italy; [2] CERN, EP Department, Geneva, Switzerland; [3] Università di Ferrara, Ferrara, Italy

Abstract

The Medipix4 ASIC is a hybrid pixel detector developed for high-rate spectroscopic X-ray imaging and photon-counting applications. Its synchronous frame-based architecture supports multiple acquisition modes and up to sixteen DDR output links, requiring scalable off-detector electronics. This work presents a modular FPGA-based Data Acquisition (DAQ) system developed for Medipix4 characterization and detector integration.

The system is composed of a Xilinx Kintex UltraScale FPGA DAQ board and a dedicated CERN-developed Medipix4 chipboard directly interfaced through FMC connectivity. The firmware reuses the IPbus-based control path developed for the Timepix4 ASIC while implementing a dedicated Medipix4 synchronous acquisition pipeline. Sixteen independent DDR interfaces operate at selectable clock frequencies of 20, 40, 80, 160 and 320 MHz. Each detector link is connected to a deserializer implementing frame detection, header decoding and 64-bit payload reconstruction. The decoded headers allow the firmware to determine the active acquisition configuration, including counter depth, active links and payload size.

The sixteen parallel data streams are packetized and transmitted through two independent 10~Gigabit Ethernet UDP links. The aggregate detector bandwidth of 10.24 Gb/s is compatible with the measured sustained transmission throughput of 2 X 8.85 Gb/s. The firmware uses reusable open-source HDL components where possible and is distributed within the Medipix collaboration as Open Hardware under the CERN Open Hardware Licence. Ongoing developments include migration toward lower-cost FPGA platforms and support for simultaneous acquisition from multiple Medipix4 ASICs.

Abstract

We measured energy-dependent single-event-upset (SEU) rates for three field-programmable gate array (FPGA) types under neutron irradiation at the BL10 beamline of the Materials and Life Science Experimental Facility (MLF) at the Japan Proton Accelerator Research Complex (J-PARC). Two 28-nm complementary metal oxide semiconductor (CMOS) devices and one 65-nm CMOS device was irradiated with neutrons over a wide energy range from meV to MeV. Dedicated firmware detected SEUs with high timing precision, and the time-of-flight (TOF) method identified the neutron energies that caused the SEUs. We estimated the neutron fluence from a PHITS simulation of the beam spectrum and normalized the SEU counts to the fluence for each FPGA type.

The SEU rates clearly depended on neutron energy.
One 28-nm device had an SEU rate in the 10^{-8}-10^{-7} MeV region about one order of magnitude higher than that at 1 MeV, whereas the other devices showed no significant low-energy enhancement. Below 0.1 MeV, the SEU rate increased as neutron energy decreased, approximately following the $1/v$ dependence, where v is the neutron velocity.

The two 28-nm devices responded differently despite using the same process technology. In contrast, the 65-nm device had a low-to-high-energy change similar to that of one 28-nm device.
These results suggest that device structure or neutron-sensitive materials, rather than process technology alone, contribute to neutron-induced SEUs.

Abstract

This work presents the design and characterisation of the front-end eletronics of a wireless active personal dosimeter for interventional radiology. The device is a low-cost, single-channel sensing unit that can be replicated across the thorax, neck, hands, and eyes, providing operators with continuous dose-rate feedback at these four anatomical regions. Each dosimeter consists of a tissue-equivalent plastic scintillator coupled to a silicon photomultiplier, read out by a charge-sensitive amplifier, a semi-Gaussian shaper with pole-zero cancellation, and a peak-and-hold circuit triggered by a comparator. Power management and wireless transmission are handled by a battery-operated microcontroller, keeping the assembly compact and unobtrusive to the operator. Dose-rate data are transmitted to a remote display with visual and sound alarms. The front-end has been characterised under dark-count conditions, with a dead time of 11.6 microseconds expected to extend to approximately 20 microseconds once analog-to-digital conversion is included in the readout loop. Energy and dose calibration of the coupled detector, together with the four-channel graphical interface, are the next development steps.

FPGA firmware for ³He resistive wire tube readout with CAEN R5560 ADC. (#2794)

Davide Raspino[1], Andrea Abba[2], Erik Schooneveld[1], Stefano Carsi[2], Jeff Sykora[1]

[1] UKRI- STFC, ISIS, Chilton Didcot, UK; [2] Nuclear Instrument, Comom, Italy

Abstract

This work presents the development of a versatile FPGA firmware for the readout of ³He resistive wire tubes widely used in neutron scattering instruments. These detectors are deployed in large numbers across major neutron facilities, including ISIS, ILL, SNS, FRM2, ESS, MLF, and CNCS.

In typical configurations, detector signals are first conditioned by front-end preamplifiers located near the tubes, then digitized by ADC systems positioned up to 40 m away. The FPGA-based processing extracts pulse amplitudes to determine the neutron interaction position along the detector. The implemented system is based on the R5560 ADC, operating at a sampling rate of 125 MHz.

The firmware, developed using SCI-Compiler, is organized into two main blocks: signal processing and data transmission. The signal processing stage includes baseline correction and gain scaling to maximize ADC dynamic range, followed by configurable filtering. The latter consists of cascaded moving-average integrators and a differentiator, with user-defined parameters (number and length of filters) adjustable via control registers to accommodate different instrument requirements.

To ensure compatibility with both legacy and next-generation data acquisition systems, the firmware supports multiple communication interfaces. At ISIS, the ADC serial interface is currently used for integration with the existing Data Acquisition Electronics (DAE), as demonstrated on the OSIRIS instrument. In parallel, a high-throughput UDP-based optical fibre link has been developed for future deployment, including WISH and µRWELL-based detector systems. Additionally, a TCP/IP Ethernet interface provides a flexible solution for diagnostics and lower-rate data acquisition.

This architecture enables a scalable and adaptable readout solution for current and future neutron detector systems.

LDMX Silicon Tracker Data Acquisition System (#2807)

Benjamin Reese, Timothy K. Nelson, Matthew Gignac, Christos Bakalis

SLAC National Accelerator Laboratory, Menlo Park, USA

Abstract

The Light Dark Matter eXperiment (LDMX) is a proposed fixed-target experiment that will search for sub-GeV dark matter using a missing-momentum signature in high-rate electron interactions. Its Silicon Tagging Tracker (STT) and Silicon Recoil Tracker (SRT) measure incoming and outgoing charged particles around the target, providing trajectory and momentum information needed to identify events with invisible final-state particles and reject backgrounds. The Tracker data acquisition (DAQ) system is built around APV25-based silicon strip modules, front-end boards (FEBs), and a Bittware PCI Express back end integrated with the common LDMX timing, fast-control, and event-building infrastructure. Each FEB distributes APV25 clock, trigger, reset, I2C control, low-voltage power, and sensor bias. It also digitizes APV25 analog streams, formats three-sample channel records, and transmits Tracker event records to the back end. The architecture is constrained by the APV25 pipeline latency and must preserve bunch timing while scaling to the final multi-FEB Tracker. During the 2025 LDMX test at SLAC End Station A, a Tracker DAQ vertical slice operated one FEB with four silicon Hybrid modules and the Bittware back end. The system acquired coherent data with other LDMX subsystems, demonstrated stable noise performance, was timed in to beam, and observed beam-induced hits with the expected timing behavior.

Latest Upgrades and Operation of the Neutron Veto Data Acquisition System for the XENONnT Experiment (#2929)

Stefano Mastroianni, on behalf of the XENON Collaboration

INFN, Sec. Naples, Naples, Italy

Abstract

The Neutron Veto (NV) of the XENONnT experiment is a gadolinium-doped water Cherenkov detector surrounding the central xenon time projection chamber (TPC). It is instrumented with 120 photomultiplier tubes (PMTs) to reduce the nuclear recoil background induced by radiogenic neutrons originating from detector materials, which can mimic WIMP-like signatures. During the third science run (SR2), conducted between October 2023 and March 2025, XENONnT achieved a significantly reduced background configuration. In particular, the neutron background was suppressed by loading the water tank with 500 ppm of gadolinium sulfate, resulting in an approximately twofold reduction compared to earlier runs performed with pure water. Following maintenance activities initiated in summer 2025, the detector is currently being recommissioned in preparation for the next science run. This work presents the latest upgrades and the operational performance of the NV data acquisition (DAQ) and online processing systems. The NV DAQ is based on a fully triggerless architecture in which PMT waveforms are continuously digitized, enabling software-based coincidence searches within time windows of several hundred nanoseconds.To enhance long-term reliability and stability, the DAQ system has been upgraded with new-generation CAEN PCIe readout cards. Concurrently, the front-end server has been upgraded to ensure compatibility with latest operating systems, while improving fault tolerance, system monitoring, and integration with the experiment-wide online processing system. A further improvement is the deployment of a dedicated FPGA-based monitoring board for the NV data readout. This board processes digitizer monitoring signals such as buffer occupancy, busy and flow-control flags, timing and synchronization signals, and error conditions during both science data taking and calibration runs, enabling continuous checks of DAQ performance and stability.

Abstract

Lithium Indium Phosphorus Selenide ($LiInP_2Se_6$) has emerged as a promising semiconductor material for neutron detection due to its high neutron capture cross-section, suitable bandgap, and favorable charge transport properties. This work reports on the development of a modular $LiInP_2Se_6$ detector prototype for single-crystal diffractometry (SCD) applications. The prototype consists of an 8 × 2 array of $LiInP_2Se_6$ strip sensors with a 300 µm pitch configuration integrated onto a custom sensor baseboard. Initial sensor characterization includes electrical IV measurements and preliminary radiation-response evaluation. The sensors are coupled to a dual-ASICs daughterboard based on VATAGP7 ASICs for signal readout and processing, while detector control and data acquisition are managed through the LISeDAQ acquisition system. This work demonstrates the integration of $LiInP_2Se_6$ sensors, front-end electronics, and acquisition hardware into a scalable detector module architecture toward future high-resolution SCD detector systems.

Improvement of Ambient dose equivalent rate Estimation for Airborne Radiation Monitoring Using Artificial Neural Networks with Vegetation and Topographic Information (#1454)

Ayumu Miyahara, Miyuki Sasaki, Kazuhiro Suzuki, Yuki Morishita, Hironori Funaki

Japan Atomic Energy Agency, 1. Collaborative Laboratories for Advanced Decommissioning Science, Minamisoma, Japan

Abstract

In airborne radiation monitoring using unmanned aerial vehicles conducted in Japan following the Fukushima Daiichi nuclear power plant accident, a flat-source model is used to estimate the ambient dose equivalent rate at ground level from count rates. However, its assumptions are not suitable for mountainous and forested areas. To improve reliability in these areas, an artificial neural network was constructed that incorporates topographic and

vegetation information as input variables in addition to count rate information, and its impact on estimation performance was evaluated.
The ambient dose equivalent rate map generated by the artificial neural network model reproduced spatial variation in more detail compared to the map created by the flat-source model. Vegetation information helped distinguish between forests and open land, contributing to improved estimation accuracy and precision. Topographic information reduced errors in mountainous areas where the relative position of the detector and the ground changes drastically. An artificial neural network incorporating this information can contribute to identifying hotspots and determining whether evacuation orders can be lifted for small areas.

Explainable Radionuclide Identification Using FWHM-Aware Adaptive Banding in Gamma-Ray Spectroscopy (#1543)

Seoyun Jang[1], Gyohyeok Song[1], Uijin Lee[1], Jeonghoon Lee[1], Daeseung Kim[2], Jisoo Kim[1], Gyuseong Cho[1]

[1] KAIST (Korea Advanced Institute of Science and Technology), Department of Nuclear and Quantum Engineering, Daejeon, South Korea; [2] Pusan National University, Nuclear Systems Major, School of Mechanical Engineering, Pusan, South Korea

Abstract
Machine learning has shown strong potential for radionuclide identification using gamma-ray spectroscopy. However, its black-box nature limits the physical interpretation of model predictions. In this study, a spectroscopy-tailored explainable artificial intelligence (XAI) framework for a 1D-CNN-based radionuclide identification model was investigated using gamma-ray spectra measured with a NaI(Tl) detector. The model was trained to classify four radionuclides: ^{22}Na, ^{60}Co, ^{137}Cs, and ^{54}Mn. To identify the spectral regions contributing to the CNN predictions, Grad-CAM, LIME, and Kernel SHAP were applied. In particular, because perturbation-based XAI methods are strongly affected by the definition of input features, two spectral banding strategies were compared: conventional uniform banding and FWHM-aware adaptive banding. The results showed that compared with uniform banding, the proposed adaptive banding provided more localized and physically interpretable attribution results in several cases. These findings suggest that detector-resolution-aware banding can improve the reliability and interpretability of XAI for gamma-ray spectroscopy.

Source-Transferable Machine Learning-based Pulse Shape Discrimination in 3D-Printed Plastic Scintillators (#1703)

Vivek Anand, Kuneh Shah, Anil K. Gourishetty

Indian Institute of Technology Roorkee, Roorkee, India

This work was supported by the Ministry of Higher Education (MHRD), Government of India.

Abstract

This work demonstrates source-transferable neutron-gamma pulse-shape discrimination in 3D-printed plastic scintillators using compact deep neural networks trained on experimental waveforms. Additively manufactured plastic scintillators are attractive for application-specific neutron detectors because printing can produce nonplanar and architected geometries. However, their pulse shapes can depend on resin chemistry, dopant loading, and curing conditions. Therefore, discrimination algorithms validated on conventional liquid or cast plastic scintillators cannot be assumed to transfer directly to printed scintillators. Pulses were collected from ^{252}Cf and AmBe sources using CAEN DT5751 and DT5730 digitizers, respectively, and analyzed using charge-comparison pulse-shape discrimination, unsupervised clustering, tree-based classifiers, one-dimensional convolutional neural networks, and fully connected deep neural networks. Charge-comparison methods were limited to 92-93% accuracy for the more overlapping ^{252}Cf dataset, whereas the optimized network used smoothed, peak-aligned, amplitude-normalized waveforms and achieved 99.55% test accuracy on ^{252}Cf. Without retraining, the same model achieved 99.91% inference accuracy on the independent AmBe dataset. Peak alignment was found to be essential as AmBe inference accuracy increased from 88.11% for unaligned raw waveforms to 99.91% for aligned waveforms. These results establish peak-aligned waveform learning as an effective route for robust neutron-gamma discrimination in 3D-printed plastic scintillators.

Spectro-Temporal Gamma-Ray Anomaly Detection with Context-Adaptive Background Modeling (#2215)

Hannah Parrilla, Mark Bandstra, Reynold Cooper

Lawrence Berkeley National Laboratory, Berkeley, USA

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Berkeley National Laboratory (LBNL) under Contract DE-AC02-05CH11231. The project was funded by the U.S. Department of Energy, National Nuclear Security Administration, Office of Defense Nuclear Nonproliferation Research and Development.

Abstract

Gamma-ray anomaly detection and identification in complex environments requires background models that are accurate, robust to environmental variation, and interpretable enough to support adaptation given contextual information. We present Gaussian Process Prior NMF (GPP-NMF) spectro-temporal background modeling, combining the physically meaningful structure of Non-negative Matrix Factorization (NMF) in the spectral dimension with a Gaussian process prior (GPP) in the temporal dimension, parameterized by a smoothing hyperparameter λ_T. Evaluated on RADAI synthetic mobile search data, GPP-NMF outperforms standard spectral NMF in the low false alarm rate regime of operational interest, with a single fixed calibrated λ_T. We validate a principled approach for λ_T adaptation to contextual information by showing that the power spectrum of the logarithm of the total building solid angle seen by the detector — extractable from camera data in real time — closely matches the GPP prior power spectrum. Full contextual integration results, including on real-world data, will be presented.

Generative Overlay Augmentation for Robust Structural Region Segmentation in Dual-Energy X-Ray Cargo Container Imagery (#2263)

Yeon-Wook Kim, Kiyoung Kim, Trinh T.D. Pham

Infiniq, AI Lab, Seoul, South Korea

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT, KCS) (IRIS RS-2025-25459707).

Abstract

Non-intrusive inspection of cargo containers via dual-energy X-ray radiography increasingly faces threats concealed within the container's own structural void spaces, making segmentation of the structural region a necessary prerequisite for downstream anomaly detection. Two compounding factors hinder this task: inconsistent geometric distortion across operational scans, and path-integral structure–cargo overlay that prevents pixel-level human annotation in densely loaded regions. We formulate the task as binary segmentation and propose a regionwise generative overlay augmentation pipeline, in which Stable Diffusion is adapted via a three-stage scheme—LoRA, ControlNet, and inpainting—to synthesise structure–cargo overlay imagery. Polygon annotation is partitioned by visual confidence: structural polygons supply segmentation labels and ControlNet conditions, while cargo polygons serve as inpainting masks. The central hypothesis is that a model trained with the proposed structure–cargo overlay augmentation outperforms a baseline trained on real annotations alone, evaluated on two test partitions defined by the visual clarity of structure–cargo separation under overlay: Easy (clearly distinguishable) and Hard (separation challenging but feasible).

Development of Realistic Gamma-ray Spectrum Database Using Geant4 and U-Net-based Sim-to-Real Translation (#2356)

Geon Kim[1,2], Junseong Hwang[1,2], Dae yang Oh[1,2], Chanho Kim[3], Jung-Yeol Yeom[1,4]

[1] Korea University, Department of Bioengineering, Seoul, South Korea; [2] Korea University, Interdisciplinary Program in Precision Public Health, Seoul, South Korea; [3] Korea Atomic Energy Research Institute, Daejeon, South Korea; [4] Korea University, School of Biomedical Engineering, Seoul, South Korea

Abstract

Reliable gamma-ray spectrum databases are needed for data-driven radioisotope identification, but direct measurements of accident-related or short-lived radionuclides are often limited by safety regulations and isotope availability. Geant4 can generate synthetic spectra, but simulated spectra may differ from measured detector-domain spectra because of detector response, energy resolution, gain variation, and channel-domain distortion. In this study, we evaluated a U-Net-based sim-to-real translation framework to transform Geant4-simulated spectra toward measured detector spectra. Measured detector energy-resolution broadening and channel-domain augmentation were applied before translation, and a spatial-transformer-integrated U-Net was used to compensate for gain- and offset-related channel shifts. In validation, the model achieved a mixed-isotope training mean absolute error of 0.045214 and leave-one-out mean absolute error values of 0.068125 for unseen ^{22}Na and 0.047816 for ^{137}Cs. A photopeak-based fidelity analysis showed that 44% of ^{22}Na samples and 24% of ^{137}Cs samples satisfied the defined peak-position and peak-height criterion and a peak-height difference threshold of 0.05. These results indicate that U-Net-based translation can partially reduce the sim-to-real discrepancy in gamma-ray spectroscopy, while consistent reconstruction of detailed photopeak structures remains limited.

Real-Time Nuclide Identification via Physics-Region Preprocessing (#2437)

Dongseong Shin[1], Inyong Kwon[2]

[1] Korea Atomic Energy Research Institute, Department of Advanced I&C Research, Daejeon, South Korea; [2] Yonsei University, Department of Radiological Science, Wonju, South Korea

This work was supported in part by the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (RS-2022-00165164, RS-2022-00144419)

Abstract

This work addresses real-time identification of gamma-emitting nuclides released outside a damaged reactor using a network of low-cost Silicon photomultiplier (SiPM)–scintillator gamma detectors. Of all fission products, only a few reach the plant exterior in amounts sufficient to produce measurable photopeaks; using the NUREG-1465 source term for Pressurized Water Reactor (PWR) severe accidents, we reduce the monitored set to the dominant nuclides ^{85}Kr, ^{131}I, ^{132}Te, ^{137}Cs, ^{60}Co, and ^{140}Ba. For this set, we design a 2K+1 physics-region preprocessing front-end that places one region of interest on each target photopeak and Compton edge, producing compact features for small downstream classifiers, including the target on-chip deep-learning core. Because direct validation on a real off-site release is impractical, we evaluate the pipeline on a K=5 surrogate set of ^{133}Ba, ^{22}Na, ^{137}Cs, ^{54}Mn, and ^{60}Co spanning the same 80 keV-to-1.3 MeV band on a NaI(Tl)-SiPM detector. On this surrogate, the 2K+1 preprocessing achieves 83.9% accuracy at 25 photopeak counts per window and 97.8% at 100, compared with 75.4% and 94.3% for a raw pulse-vector baseline.

Abstract

Vehicle-based radiation monitoring systems are widely used for environmental radiation surveillance, nuclear emergency response, and radioactive contamination mapping. Conventional systems use large-area NaI(Tl) scintillation detectors with high sensitivity for low-count-rate radiation measurements. However, they have limitations such as poor energy resolution and the inability to provide directional information of radiation sources. To overcome these limitations, this study developed a vehicle-based radiation source direction detection system using nine NaI(Tl) detectors while maintaining high sensitivity and energy resolution. The system consists of nine Φ3” × 3” NaI(Tl) detectors. Four upper-layer detectors were arranged for rapid direction identification, one center detector was used for dose assessment, and four lower-layer detectors with lead collimators improved directional accuracy. Radiation source direction was estimated using detector count-rate ratios according to incident direction and distance. An ANN-based algorithm was applied for direction estimation. System performance was evaluated using a 137Cs (100 μCi). Energy resolution and sensitivity were evaluated at 23 cm, while angular resolution tests were conducted at 6 m with source angles varied from 0° to 90° at 10° intervals. The developed system showed approximately 6.8 times higher detection sensitivity than a conventional large-area NaI(Tl) detector system. The angular resolution was evaluated as 45° and 10° for the upper and lower detector layers, respectively, confirming the feasibility of radiation source direction detection in a vehicle-based system. Future work will focus on miniaturization through compact optical sensors, detector rearrangement, and signal-processing optimization.

NSS-01-171

Wavelet optimisation for improved photopeak extraction in low-count gamma-ray spectra (#2656)

James Biggs, Caroline Shenton-Taylor

University of Surrey, School of Maths and Physics, Guildford, UK

Abstract

Detector networks are a potential method of surveillance of radiological material moving through urban environments. Such a network would require ways of automatically assessing collected spectra for non-background isotopes, particularly in count-starved spectra collected in environments with complex backgrounds. In 2018, the London-based SIGMA trial gathered 1.5 billion one-second gamma spectra using both stationary and mobile scintillator detectors. This work presents a wavelet analysis method optimised for use with count-starved gamma spectra. A range of ^{137}Cs spectra were collected, both experimentally and simulated in Geant4, and combined with real-world SIGMA background data. A continuous wavelet transform was conducted on each spectrum, producing an associated scalogram with wavelet transform modulus maxima lines arising from spectral features. By using the ’straightness’ of these lines, it was shown to be possible to identify the presence of ^{137}Cs with 95% accuracy, with a number of false positive identifications. Constraining certain metrics within the method reduced the number of false positives at the expense of overall detection accuracy. UK Ministry of Defence © Crown Owned Copyright 2026/AWE

Real-Time Particle Hit Detection Using a 1D Convolutional Neural Network on a CAEN FPGA-Based Digitizer (#2722)

Carlo Tintori[1], Matteo Brini[1], Alberto Potenza[1], Ferdinando Giordano[1], Marco Zanetti[2,3], Andrea Triossi[2,3], **Michail Sapkas**[2,3]

[1] CAEN S.p.A., Viareggio, Italy; [2] University of Padova, Physics and Astronomy, Padova, Italy; [3] INFN Padova, Padova, Italy

Abstract

This study proposes a 1D Convolutional Neural Network (CNN) architecture designed for real-time particle hit detection, moving beyond traditional rigid triggering thresholds. By processing continuous data streams, including high-noise environments, our model demonstrates superior sensitivity in low Signal-to-Noise Ratio (SNR) regimes and pile-up events. We demonstrate that this approach successfully identifies particle signals and provides precise temporal metadata in real time, offering a robust alternative to conventional signal processing methods. Performance was evaluated on a scintillating detector.

Development of an ANN-based Gamma-ray Spectrum Correction Algorithm for PVT Detectors (#2762)

Jiwon Ra, Juwan Kang, Yoon Soo Chung, Yong Hyun Chung

Yonsei University, Department of Radiation Convergence Engineering, Wonju, South Korea

This research was supported by the Regional Innovation System & Education(RISE) program through the Gangwon RISE Center, funded by the Ministry of Education(MOE) and the Gangwon State(G.S.), Republic of Korea.(2025-RISE-10-006)

Abstract

Environmental radiation monitoring systems require detectors that can measure radiation in real time and rapidly identify radionuclides. This study developed an artificial intelligence–based spectrum Correction algorithm that converts gamma-ray spectra acquired from polyvinyl toluene (PVT) detectors with limited energy resolution into

spectra comparable to those of NaI(Tl) detectors. The proposed model used an artificial neural network (ANN)-based multi-layer perceptron (MLP) regressor with two hidden layers, each containing 64 nodes. Rectified Linear Unit (ReLU) and Adaptive Moment Estimation (Adam) were employed as the activation function and optimizer, respectively. The model was trained using PVT spectra as input and NaI(Tl) spectra as target output data to learn the spectral relationship between the two detector systems. Training datasets were generated using Geant4 Application for Tomographic Emission (GATE) for four radionuclides: Co-57, Ba-133, Cs-137, and Co-60. The simulation results demonstrated that the proposed model successfully generated NaI(Tl) photopeak features from PVT spectra. Representative results for Cs-137 yielded a Pearson correlation coefficient of 0.9996 and a root mean square error (RMSE) of 0.0038. Additionally, the energy resolutions at the 662 keV photopeak were found to be 5.94% for the actual NaI(Tl) spectrum and 5.96% for the predicted spectrum, indicating that the two spectra have highly consistent energy resolution characteristics. These results imply that the proposed model can generate spectra with characteristics comparable to those of NaI(Tl) detectors while maintaining the practical benefits of PVT detectors for radiation monitoring applications.

measurement-guided x-ray image restoration using fourier stochastic differential equations (#2948)

Seokwon Oh, Junho Lee, Seungjun Yoo, Jeonghyeon Kim, Ho Kyung Kim

Pusan National University, school of mechanical engineering, Busan, South Korea

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) under Grant RS-2024-00340520. S. Oh was supported by the Basic Science Research Program through the NRF funded by the Ministry of Education under Grant RS-2024-00408137.

Abstract
Industrial X-ray imaging for nondestructive inspection requires high spatial resolution and high sensitivity, but phosphor-based detectors face a trade-off because increased phosphor thickness improves X-ray absorption while degrading spatial resolution through optical spreading. This study investigates a measurement-guided Fourier stochastic differential equation for detector X-ray image restoration. The proposed method defines a degradation path in the Fourier domain using measured detector characteristics. The relative modulation transfer function (MTF) models deterministic resolution loss, and the measured noise power spectrum guides stochastic perturbation. A neural restoration network is trained to reconstruct high-resolution images from intermediate degraded states conditioned on low-resolution observations. Experiments on printed circuit board X-ray images compared the

proposed method with Wiener filtering, a regression baseline, and a conditional diffusion model (CDM). The proposed method improved low-resolution images and achieved image domain restoration quality comparable to the regression baseline and better than Wiener filtering, while CDM showed slightly lower structural fidelity in representative regions. Frequency domain analysis using MTF, contrast transfer function (CTF), and NNPS showed that both CDM and the proposed method closely followed the high-resolution MTF and that the proposed method showed higher CTF recovery in the mid-to-high frequency range. These results indicate that X-ray image restoration methods should be assessed using both image domain metrics and frequency domain characteristics.

A General-Purpose Radionuclide Identification Model for HPGe Gamma-Ray Spectrometry (#3209)

Jim Zickefoose, **Henrik Persson**, Cameron Cianci

Mirion Technologies (Canberra) Inc, Physics, Meriden, USA

Abstract
Radionuclide identification in high-purity germanium (HPGe) gamma-ray spectra can be a challenging and time-consuming task, particularly when complex samples contain many radionuclides that produce overlapping spectral features. In addition to sample emissions, HPGe detectors measure contributions from naturally occurring and environmental radionuclides, referred to as background. The measured sample spectrum is therefore the sum of sample and background contributions, and in most applications it is desirable to identify only the radionuclides present in the sample itself. While background subtraction is commonly performed using a separate background measurement, accurate identification near critical detection limits remains difficult, especially for low-count or cluttered spectra.
We present a Siamese Neural Network (SNN)–based approach for radionuclide identification with background subtraction in HPGe gamma-ray spectra that is generalizable to many detector models and geometries. By directly learning a similarity metric between foreground and background spectra, the method enhances sensitivity to weak spectral features while maintaining low false-positive rates.
The network is trained on a large dataset containing spectra from over 500 radionuclides, generated using Monte Carlo simulations spanning more than 50 detector and geometry combinations and augmented with measured background data. We present the data generation methodology, training procedure, and performance results on

both simulated and measured spectra. The results demonstrate that the SNN approach achieves performance comparable to or exceeding that of traditional spectral analysis techniques. This work provides a foundation for robust, automated radionuclide identification across diverse measurement conditions.

High-Fidelity 3D MCNP Modeling for Waste Classification in PWRs

(#1189)

Changyeon Yoon

Korea Hydro & Nuclear CO., LTD, Central Research Institute, Daejeon, South Korea

Abstract

Accurate classification of radioactive waste is critical for determining disposal costs and ensuring safety during nuclear power plant decommissioning. However, generic models with simplified geometries and material compositions can lead to systematic misclassification. In this study, a high-fidelity 3D MCNP model of a pressurized water reactor (PWR) was developed to evaluate activation source terms and classify waste based on IAEA Safety Standards Series. The model includes the reactor pressure vessel (RPV), reactor vessel internals (RVI), and bioshield concrete, enabling realistic representation of complex structures. Activation analysis shows that Fe-55, Co-60, and Mn-54 are the dominant radionuclides in both the RPV and bioshield, qualitatively aligning with widely recognized reactor activation data and thereby validating the developed model. Based on specific activity, Fe-55

accounts for over 99% in both structures. However, applying radionuclide-specific activity limits results in a dramatic shift in the dominant contributor. In the bioshield concrete, the contribution of Fe-55 decreases from over 99% to approximately 16%, while C-14 becomes dominant at approximately 76%. This indicates that classification based solely on specific activity can lead to fundamental misclassification. The RPV is classified as low-level waste (LLW), whereas the bioshield meets the criteria for very low-level waste (VLLW). In contrast, generic models fail to accurately represent the reactor configuration, which can result in over-classifying the bioshield as LLW. The high-fidelity approach provides a quantitative basis for reclassification, directly contributing to the reduction of disposal volume. These results demonstrate that high-fidelity activation modeling is essential not only for improving classification reliability but also for avoiding systematic overestimation of waste classes and enabling more economically efficient decommissioning strategies.

Six-Degree-of-Freedom Pose Estimation for Safety Monitoring in a Nuclear Glovebox (#1287)

Lewis Mead, Charlie Kind, Tom Scott

University Of Bristol, Interface Analysis Centre, Bristol, UK

Thanks to my supervisors Charlie Kind and Tom Scott, and colleagues at the Interface Analysis Centre, for their guidance, technical support, and feedback throughout this work.

Abstract

Nuclear glovebox monitoring must recognise not only which objects are present, but whether their position and orientation indicate an operationally relevant state, such as an inverted container, a handled tool, or an object moving close to a glove during potentially hazardous work. This paper evaluates a two-camera six-degree-of-freedom vision pipeline for advisory operator support in a tabletop analogue of a nuclear glovebox containing a can, pliers, and screwdriver. Offline colour-and-depth pseudo-labels are generated and filtered to train a lightweight object detector and keypoint regressor. During live operation, the system performs object detection, keypoint-based pose recovery, masked depth refinement, temporal smoothing, and safety-state logging. On the validation split, the detector achieved 99.3% mean average precision at an intersection-over-union threshold of 0.5, and the live keypoint-and-depth-refinement pipeline ran at 8.5 frames per second on constrained hardware. These results show that pose-aware monitoring can support prototype glovebox alarms and auditable event records without running a high- capacity pose model online, suggesting a practical route toward advisory systems that improve situational awareness and post- task review while preserving operator judgement. Before such systems could be used operationally, further work is required to establish independent ground truth, model articulated tools, validate longer-term reliability, and build the necessary safety case.

Photonuclear Processes in a Tungsten Matrix Collimator for Spatially Fractionated Radiation Therapy (#1326)

Igor E. Anokhin, Dmytro Ramazanov

Institute for Nuclear Research, Kyiv, Ukraine

Abstract

Spatially fractionated radiation therapy using tungsten matrix collimators enables high peak-to-valley dose ratios and improved normal tissue sparing. At photon energies near 25 MeV, photonuclear interactions in tungsten induce activation and produce secondary neutrons, potentially affecting both dosimetric performance and radiation safety. In this work, these processes were investigated using FLUKA Monte Carlo simulations of a modular tungsten-matrix collimator irradiated by a 25-MeV photon beam. Secondary neutron fluence distributions, energy spectra, and absorbed-dose maps in a silicon detector plane were evaluated and normalized to a photon fluence of approximately 1×10^{9} cm^{-2}. The calculated absorbed-dose profile exhibits a pronounced mini-beam structure with a peak dose of 6.16×10^{-4} Gy, a valley dose of 2.53×10^{-5} Gy, and a peak-to-valley dose ratio of 24.4. Neutron production is highest at the entrance to the collimator and decreases significantly beyond approximately 5 cm along the beam path, indicating substantial attenuation within the 9 cm tungsten structure. Folding the neutron spectra with energy-dependent fluence-to-dose conversion coefficients yields an ambient dose equivalent of 102 μSv in the collimator region and 0.62 μSv in the phantom region for the same irradiation.

The results demonstrate that photoneutron generation is strongly influenced by the collimator configuration and exhibits distinct spatial and spectral characteristics. Photoneutrons contribute to the dose outside the primary irradiation field, thereby increasing the valley dose and affecting the achievable peak-to-valley dose ratio. These

findings underscore the importance of accounting for photonuclear effects during collimator optimization and shielding design for high-energy photon mini-beam therapy systems.

A Low-Energy X-ray Transmission Imaging Method for Detecting Metallic Microparticles in Single-Layer $LiFePO_4$ Batteries (#1517)

Dehao Wang, Yigang Yang

Tsinghua University, Department of Engineering Physics, Beijing, China

The authors would like to thank the Department of Engineering Physics, Tsinghua University, for experimental support and helpful discussions.

Abstract

Metallic foreign particles are critical safety hazards in lithium-ion battery manufacturing. To address the difficulty of detecting metallic microparticles in single-layer $LiFePO_4$ cells, this work proposes a nondestructive detection method based on low-energy X-ray transmission imaging. Cu, Fe, and Ni particles are analyzed through attenuation modeling and simulation to evaluate the effects of photon energy, particle material, and particle thickness on transmission contrast. Preliminary imaging experiments are performed using 40keV X-rays, and weak abnormal signals are extracted by normal-sample normalization, filtering enhancement, threshold segmentation, and local SNR analysis. The results show that metallic microparticles can produce detectable local attenuation anomalies in low-energy X-ray images.

Abstract

In non-destructive testing (NDT), simulation is used to study radiation–matter interactions for various cases. CIVA software includes a radiographic testing (RT) module, which combines analytical and Monte Carlo (MC) approaches. The analytical component models primary photons, while the MC component handles scattered photons — a process that can become computationally intensive in complex configurations. Building on this, we introduce an estimator based on a split exponential track length method (seTLE) in the MC component of CIVA-RT, designed to reduce statistical variance and computational cost. This next-event estimator increases the probability of photon contributions to the detector by creating multiple pseudo-photons during the simulation. Its performance is evaluated using a convergence index and a Figure of Merit. Three configurations are studied: a simple configuration, a step wedge configuration with a distant detector, and an industrial weld case. Results show that the estimator provides significant efficiency gains. A detailed analysis of seTLE simulation shows that rare high-weight photons can cause sudden signal variations. These results demonstrate that the approach provides efficiency gains, making high fidelity simulations more tractable in industrial contexts.

Development of a spectral unmixing method for gamma-ray spectra analysis : application to airborne measurements (#2081)

Killian Castillo[1], Luc Patryl[1], Charles-Philippe Mano[1], Hugues Paradis[1], Frédérick Carrel[2], Jérôme Bobin[3]

[1] CEA, DAM-DIF, ARPAJON, France; [2] CEA, LIST, SACLAY, France; [3] CEA, IRFU, SACLAY, France

Abstract

The CEA develops and uses airborne detectors to carry out gamma mapping missions for various private and public entities, and various national and international authorities. The main objectives of these missions are : site monitoring (natural and anthropic contributions to environmental radioactivity), mapping contaminated areas, detecting and identifying radionuclides and radioactive sources.

Methods for analyzing the spectra acquired during these missions are being studied, with a view to improve decision thresholds and detection limits for various radionuclides of interest. A spectral analysis method called "spectral unmixing" has been developed, using a full spectrum analysis instead of the reference method based on regions of interest. This algorithm takes into account the response of the detector under study to an individual radionuclide, and estimates the proportions of the different radionuclides using a likelihood estimator. This method was shown to be accurate for reconstructing radionuclide activities, with improved sensitivity compared to the reference method.

The application of this algorithm to airborne detectors raises a number of challenging problems, such as taking into account the variability of spectral signatures linked to the environment and source shielding. An algorithm has been developed to address this problem. The algorithm was validated on simulated and experimental data, and improved the results of an airborne measurements campaign. This method can be implemented on the measurement system for real-time radionuclide identification.

Hybrid Semantic–Keyword Analysis for the Classification of Nuclear Fuel Cycle Activities Using Open-Source Information (#2241)

Yeon Woo Lee[1], **Seung A Choi**[1], Seul Ah Kim[1], Chul Hee Min[2], Yong Hyun Chung[2], Jae Joon Ahn[1]

[1] Yonsei University, Division of Data Science, Wonju, South Korea; [2] Yonsei University, Department of Radiation Convergence Engineering, Wonju, South Korea

This work was supported by the Nuclear Safety Research Program through the Korea Foundation Of Nuclear Safety using the financial resource granted by the Nuclear Safety and Security Commission of the Republic of Korea (No. RS-2026-25538205)

Abstract

This study proposes a hybrid semantic–keyword analysis framework for automatically identifying and classifying nuclear fuel cycle-related activities using open-source text data. In the safeguards system of the International Atomic Energy Agency, continuous monitoring and analysis of nuclear fuel cycle activities are required; however, existing approaches rely heavily on expert-driven manual review, limiting efficient processing of large volumes of unstructured text data. To address this issue, nuclear fuel cycle-related news articles collected from Google News were used to construct profiles for seven nuclear fuel cycle activities. Each activity was represented by combining semantic information derived from Sentence-BERT embeddings with keyword importance obtained using class-based TF-IDF. Subsequently, key sentences were extracted from IAEA news articles, and activity classification was performed by integrating semantic and keyword similarity for each activity category. Performance evaluation results showed that the proposed method achieved a Top-1 accuracy of 57.14%, a Top-3 accuracy of 85.71%, and a mean reciprocal rank of 0.738. In addition, the actual activity category was generally included within the top candidate groups, showing that the proposed framework reflects the semantic relationships and complex characteristics among nuclear fuel cycle activities. This study demonstrates the feasibility of automating open-source-based nuclear fuel cycle activity analysis and suggests the potential for future extension to an Additional Protocol-based automatic declaration target identification system. The results also highlight the applicability of data-driven analytical approaches for safeguards and regulatory support.

Selective Use of Directionally Informative Non-Photopeak Events for Low-Count Industrial Gamma Imaging (#2392)

Linxin Lei, Debin Zhang, Yuxi Zhang, Zhenlei Lyu, Tianyu Ma

Tsinghua University, Beijing, China

Abstract

High-performance industrial gamma imaging under count-limited conditions is challenging, particularly for medium- and high-energy radionuclides where photopeak statistics are limited. However, some non-photopeak Compton-related events still retain directional information. We propose a directionally informed multi-energy-window reconstruction method that selectively incorporates such events. Monte Carlo spectral decomposition was used to define energy windows and estimate useful-event fractions. Window-specific projection data were paired with matched system matrices and jointly reconstructed using weighted MLEM.

The method was evaluated with a self-collimating industrial gamma camera for ^{137}Cs imaging. In point-source experiments, 30 s multi-window reconstruction achieved localization accuracy comparable to 90 s photopeak-window-only MLEM. In structured-source and short-frame dynamic imaging, it reduced background artifacts and improved localization stability. These results show that selective use of directionally informative non-photopeak events can improve event utilization and reconstruction robustness under low-count industrial gamma imaging conditions.

An Optical Surrogate Framework for Three-Dimensional Fusion Source Reconstruction (#2548)

Zhong Zhang[1,2], Yigang Yang[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Tsinghua University, Key Laboratory of Particle and Radiation Imaging, Ministry of Education, Beijing, China

Abstract

Three-dimensional reconstruction of fusion neutron sources is critical for diagnosing burn-region morphology and implosion asymmetry in inertial confinement fusion, yet the recoverable morphology is severely limited by sparse and geometrically constrained diagnostic views. This work proposes an optical surrogate framework to study information-driven sparse-channel layout design for fusion neutron source reconstruction, offering controllable source morphology, low cost, and ease of iteration compared to direct neutron diagnostics. The core motivation is to treat limited-view reconstruction not only as an inverse-algorithm problem, but also as a constrained layout-design problem. A conceptual design employing Latin hypercube sampling generates candidate layouts within admissible geometries, followed by greedy selection. The optical surrogate tests the shared inverse-problem structure using movable point-like optical sources, directional fiber channels, rather than reproducing neutron transport physics. Preliminary fiber-response measurements reveal finite-acceptance soft-channel behavior with a transverse full width at half maximum of approximately 2.7 mm. Theoretical reconstruction using a discrete multi-point-source design yields a detector-domain residual of 0.038, a source-correlation coefficient of 0.998, and a maximum relative strength-ratio error of approximately 7.2%. These results establish a forward-model basis for subsequent layout optimization and future migration to neutron-response matrices.

Adaptive Tetrahedral Mesh Reconstruction for Industrial Computed Tomography (#2942)

Junho Lee, Yoonsang Hong, Seungjun Yoo, Seokwon Oh, Ho Kyung Kim

Pusan National University, Computational X-ray Imaging Laboratory, School of Mechanical Engineering, Busan, South Korea

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) under Grant RS-2024-00340520. J. Lee and Y. Hong were supported by the Korea Institute of Energy Technology Evaluation and Planning (KETEP) and the Ministry of Climate, Energy and Environment (MCEE) of the Republic of Korea under Grant RS-2024-00398425.

Abstract

Industrial X-ray computed tomography (CT) is widely used for non-destructive inspection and generation of geometric models. However, conventional voxel-based CT reconstruction on a fixed Cartesian grid causes partial-volume blurring and possible geometric errors when converted into surface or CAD models. This work presents an interface-adaptive tetrahedral mesh-based iterative reconstruction framework for industrial CT. The method estimates nodal attenuation coefficients directly on an unstructured mesh. X-ray projection and backprojection are performed by an NVIDIA OptiX-accelerated projector, which computes ray-mesh intersections, segment lengths, and barycentric weights, and backprojects residuals using the SIRT algorithm. To improve boundary representation, the reconstructed field is used to detect interface-related edges, locally refine the mesh, and displace vertices. For each candidate vertex, a local attenuation-gradient direction is estimated from neighboring nodes. The neighbors are divided across the estimated normal, and the vertex is shifted toward the attenuation mid-level between regions while enforcing element quality constraints. Simulated projection studies showed the proposed adaptive mesh reconstruction preserved overall structure while producing sharper material boundaries than voxel-based SIRT. Global structural similarity improved, particularly in regions containing material interfaces. These results indicate the framework reduces boundary blurring, supporting more accurate defect sizing and dimensional measurement in industrial testing.

Forward Simulation of High-Energy XPCI Using XRM-Derived Semiconductor Package Phantoms (#2980)

Uijin Lee[1], Seoyun Jang[1], Daeseung Kim[1,2], Sangho Lee[1], Yeaeun Kim[1], Gyohyeok Song[1], Jeonghoon Lee[1], Gyuseong Cho[1], Jisoo Kim[1]

[1] Korea Advanced Institute of Science and Technology, Department of Nuclear and Quantum Engineering, Daejeon, South Korea; [2] Pusan National University, Nuclear Systems Major, School of Mechanical Engineering, Busan, South Korea

Abstract

This study presents a forward simulation of high-energy X-ray phase-contrast imaging (XPCI) for semiconductor package inspection using an X-ray microscopy (XRM)-derived structural phantom. A projected phantom from an experimental laboratory XRM reconstruction stack was used as a geometry prior rather than quantitative material ground truth. The projected grayscale phantom was percentile-normalized and mapped to simplified Cu/Si refractive-index distributions. Under the proposed long-beamline high-energy synchrotron XPCI conditions, the simulated XPCI intensity and retrieved phase images reproduced characteristic package structures, including stacked layers and metal interconnect regions. The finite-source-induced blur was on the order of the detector pixel size, while the selected intra-bump feature showed higher local visibility in the retrieved phase image than in the simulated intensity image. This work extends idealized-phantom simulations to a laboratory-XRM-reconstructed semiconductor package structure under long-beamline high-energy synchrotron XPCI conditions.

Abstract

X-ray scannings are widely adopted by customs to control containers. Transmission and backscatter X-ray imaging are often jointly employed to enhance material discrimination and detection robustness in cargo inspection systems. However, the two modalities typically operate at substantially different photon energy levels, leading to energy-dependent interaction volumes and effective source geometries that cannot be simultaneously aligned. As a result, image registration becomes a prerequisite for joint analysis and decision-making based on transmitted and backscattered measurements, yet it is fundamentally ill-posed because consistent spatial correspondence between the two imaging processes is not directly observable. In this work, we investigate this identifiability issue in joint transmission--backscatter X-ray image registration by explicitly modeling energy-dependent source geometry and imaging physics. We show that mismatched photon energies can induce structural ambiguity, such that multiple spatial alignments may remain similarly plausible under joint interpretation.

Development of a UAV-Mounted Radiation Survey System Integrating LaBr3(Ce) Detectors and LiDAR (#1003)

Young-Yong Ji, Wanook Ji, Kyungmin Kim, Myoung Jung Kim

Korea Atomic Energy Research Institute, Environmental Safety Technology Research Division, Daejeon, South Korea

This work was supported by the Ministry of Science and ICT (MSIT) of the Republic of Korea (Project No. RS-2022-00144210).

Abstract

To facilitate the highly efficient and accurate surveying of radioactively contaminated areas, this study presents the development of an advanced UAV-mounted integrated survey system capable of the simultaneous, real-time measurement of 3D geospatial information and environmental radiation data. The hardware architecture is robustly constructed, integrating two sets of two-inch LaBr3(Ce) detectors for high-resolution gamma spectrometry. This is combined with a LiDAR sensor for acquiring precise 3D terrain topography, a GPS, and a laser altimeter to ensure accurate spatial referencing. To guarantee operational stability during flight, the payload design incorporates specialized vibration-damping mounts and a lightweight 1.5-millimeter aluminum housing. Furthermore, a high-speed LTE router network was introduced to reliably handle the transmission of large-capacity data streams to the ground station.

The practical efficacy of the system was rigorously validated through extensive flight tests conducted over radioactively contaminated regions in Fukushima. When aerial measurements were mathematically converted to dose rates at one meter above ground level, the results demonstrated highly satisfactory performance, showing a strong statistical correlation with baseline data obtained using conventional backpack-type ground survey equipment. Crucially, by mapping real-time energy spectra directly onto the acquired 3D geospatial models, the system successfully enabled the comprehensive, multi-dimensional identification of specific high-level contamination hotspots. Moving forward, by integrating AI to further refine advanced topographical correction algorithms, this autonomous system is expected to significantly enhance the rapid and precise generation of contamination maps, providing critical support for emergency response.

Development of a Handheld Uranium Enrichment Analyzer Based on LaBr3 Detector and Relative Detection Efficiency Self-Calibration Method (#1069)

Guorong Liu, Hao Zhou, Jinghuai Li

China institute of atomic energy, Department of Radiochemistry, Beijing, China

Abstract

To meet the on-site inspection requirements for uranium materials, a handheld uranium enrichment analyzer based on a LaBr3 detector and the relative detection efficiency self-calibration method was developed. The adopted LaBr3:Ce crystal has a size of 38.1mm in diameter and 25.4mm in thickness, with an energy resolution of 2.9% at 662keV. The handheld uranium enrichment analyzer is equipped with a 4.5-inch touchscreen. It features overall dimensions of 145×75×58mm and a weight of 800g, supporting continuous operation for more than 8 hours. Test results from six NBS standard samples show that for uranium samples with a mass≥200g, a ^{235}U enrichment≥0.711%, and a measurement time≥1800s, the relative deviation of the measured ^{235}U enrichment is less than 8.0%. This device can be applied to the verification and measurement of ^{235}U enrichment in uranium materials.

Neutron Response Evaluation of Miniature Spherical Li-glass scintillators for Optical-Fiber-Based Detectors (#1115)

Yutaro Saito, Yuya Oshima, Wakako Kitsuki, Kenichi Watanabe

Kyushu University, Applied Quantum Physics and Nuclear Engineering, Fukuoka, Japan

This work was supported by a research grant from Murata Science and Education Foundation.

Abstract

Boron Neutron Capture Therapy (BNCT) and high-flux pulsed neutron sources such as J-PARC require reliable real-time neutron monitoring with minimal perturbation of the irradiation field. We have been developing miniature optical-fiber-based neutron detectors using small Li-glass scintillators mounted at the fiber tip. Conventionally, the scintillator pieces were prepared by crushing bulk Li-glass, producing irregularly shaped fragments that introduce geometric uncertainties and complicate quantitative response evaluation by Monte Carlo simulation. To overcome this, an aerodynamic polishing technique was established to shape Li-glass fragments into well-defined spherical particles with diameters of 100 to 500 μm without significant degradation in light yield. The spherical geometry enabled quantitative prediction of the wall effect through PHITS Monte Carlo simulations with a quenching model based on Birks' law, and the simulated pulse-height spectra showed excellent agreement with experimental data obtained from spheres of various diameters (220–450 μm). This approach provides a robust framework for the precise design and manufacturing of miniature neutron detectors for high-intensity fields.

Abstract

The Coded Cube Camera for Gamma-ray (C3G) is a 4π gamma-ray imager designed to estimate gamma-ray source distributions from direction-dependent detector response patterns. In this study, we developed a 24-detector C3G consisting of 24 HR-GAGG scintillators and applied it to a plant radioisotope (RI) imaging experiment using $^{11}CO_2$ gas. In the plant RI imaging experiment, approximately 300 MBq of $^{11}CO_2$ gas was supplied to a plant placed in an experimental chamber to image the transport of ^{11}C-labeled photosynthates within the plant. During this experiment, the C3G was placed outside the chamber, and the dynamics of $^{11}CO_2$ gas were continuously measured with an acquisition time of 1 s per measurement. As a result, the inflow of the gas into the chamber was clearly visualized. In addition, the reconstructed image intensity decreased exponentially over time. The half-life estimated from this intensity change was 20.70 min, which was in good agreement with the known half-life of ^{11}C, 20.34 min. These results demonstrate that the 24-detector C3G can visualize dynamic gaseous radioactive sources and estimate temporal changes in radioactivity from reconstructed image intensity. This capability is expected to be useful for applications such as radioactive gas leakage monitoring, environmental monitoring, and nuclear security.

Performance Evaluation of a Fast Fission Neutron Coincidence Counting System (#1196)

Yosuke Toh, Makoto Maeda, Masao Komeda

Japan Atomic Energy Agency, Nuclear Science and Engineering Center, Ibaraki, Japan

This work supported by the Decommissioning, Contaminated Water and Treated Water Management Project funded by the Ministry of Economy, Trade and Industry (METI), Japan.

Abstract
Characterization of nuclear fuel in fuel debris is essential for the decommissioning of the Fukushima Daiichi Nuclear Power Station. The fast fission neutron coincidence counting (FFCC) method, which is less sensitive to neutron absorbers than conventional thermal-neutron-based techniques, was investigated using Monte Carlo simulations with PHITS. A cylindrical unit can containing fuel debris was modeled, and four detector configurations with 24–72 liquid scintillator detectors were compared. Fast neutron coincidence counting efficiency decreased as the number of detectors decreased, whereas the quantification limit did not vary monotonically; the 56-detector configuration provided the best performance. This indicates that an optimal number of detectors exists, as gains in coincidence events are offset by reduced efficiency in distant detectors and increased background counts. Evaluation of the effective dose showed that shielding with lead and boron-loaded polyethylene reduced the dose around the system below the access limit for personnel, without significantly affecting measurement performance. These findings provide useful guidelines for the design of practical FFCC systems.

Development and Validation of Neutron Diagnostics on ASP in Support of Future Facilities (#1227)

Lucy A. Wilson, Colin Horsfield, Alex Leatherland, Gareth Davies, Thomas Harrington, Sam Morley, Simon Rice, Sebastian Tanner, Aaron Stott, Andrew Simons, William Tominey, Verity Woolhead, David Wright

AWE - Nuclear Security Technologies, Reading, UK

Abstract
The ASP neutron facility at AWE – Nuclear Security Technologies (AWE-NST) Aldermaston, is undergoing upgrades to both the accelerator beamline and the supporting diagnostics. This is driven by evolving customer requirements, particularly its increasing use as a platform for fundamental nuclear data measurements. Neutron flux monitoring on ASP is provided by fission chambers and is supported by external activation foil calibrations and internal cross-calibration measurements. A recommissioned associated-particle technique provides improved accuracy for lower-fluence measurements, while ongoing work is improving neutron spectral characterisation using a range of techniques including activation, Single crystal chemical vapour deposited diamond detectors, proton recoil and Helium - 3 spectrometers. These activities reduce uncertainties in current measurements, and establish the diagnostic techniques required for a future facility (VENTURE) capable of delivering higher fluxes and a wider range of quasi-monoenergetic neutron energies. The calibration and diagnostics strategy for the VENTURE facility is outlined, with an emphasis on delivering the well characterised source required for nuclear data experiments.

[1] Chengdu Novel Medical Equipment Ltd., Chengdu, China; [2] Tsinghua University, Beijing, China; [3] University of Science and Technology Beijing, Beijing, China

Abstract

As the demand for the detection of special nuclear materials increases, the use of imaging instruments that can sensitively image both gamma-ray and neutron signatures has become necessary. The radioactive waste streams can contain neutron-emitting radioactive materials, hence localisation of neutron sources plays an important part in nuclear decommissioning. Neutron detector design based on the MURA revealed promising results when tested in security applications. Due to the requirement of ensuring high detection efficiency for both neutrons and gamma rays, the plastic scintillator used is typically thick. As demonstrated in our previous study, the dual-layer design exhibits better imaging performance and produces fewer artifacts. In this paper, we propose a dual-layer DOI (depth of interaction) detector design and have successfully developed a prototype module. The first and second layer of the crystals are clearly resolved from the flood histograms, demonstrating its capability to provide two-layer depth encoding. The energy resolution of each layer is improved by 50% compared with that of a single-layer detector with the same thickness, and the neutron/gamma discrimination figure of merit (FOM) is also significantly enhanced. Validation and testing of the imaging performance are currently underway.

Multilayer Scintillator for Improved Gamma-ray Discrimination at Thermal Neutron Scattering Beamlines (#1365)

Ahmed Moustafa, Matthew Loyd

Oak Ridge National Laboratory, Oak Ridge, USA

This work was sponsored by the U.S. Department of Energy (DOE) Office of Science Early Career Research Program Award (KC0406021) under Contract No. DE-AC05- 00OR22725.

Abstract

Scintillator-based thermal neutron detectors are utilized at scattering beamline facilities around the world. The Anger camera is one example that was designed and deployed at Oak Ridge National Laboratory. The camera uses enriched ^{6}Li-glass (GS20) that offers advantages over the widely used ^{3}He gas proportional counters,

including sub-millimeter spatial resolution, higher count rate capability, and high neutron absorption efficiency. However, GS20 has higher γ-ray sensitivity due to its solid state, potentially reducing the neutron signal to background ratio. Gamma rejection using pulse height discrimination is feasible, but it suffers when there is greater overlapping between the neutron and gamma spectral features in intense background fields, like with certain beamline configurations. Additionally, pulse shape discrimination is unfeasible with GS20. Previous work demonstrated a new approach to discrimination by optimizing the scintillator shape and reducing its size. In this work, we demonstrate improved gamma discrimination by segmenting the GS20 scintillator layer of the Anger camera. The layer is divided into several thinner layers with the same overall thickness, and coupled together using non-scintillating quartz layers. The neutron absorption products fully deposit their energy in the GS20 layers due to their significantly shorter range compared to the Compton-scattered electrons from γ-rays that only partially deposit their energy. This allows for better separation between the respective features on the pulse height spectrum, and therefore improved discrimination, while maintaining the same high neutron absorption efficiency.

This work was supported by JSPS KAKENHI Grant Number JP25K01706.

Abstract

This study demonstrates organic scintillator-based neutron coincidence counting as a promising approach for photonuclear nondestructive assay (NDA) of nuclear materials. Four organic scintillators—organic glass scintillator (OGS), EJ-276D, stilbene, and BC-501A—were systematically evaluated in terms of fast-neutron detection efficiency, pulse shape discrimination (PSD) capability, and timing response. In addition, three-detector coincidence counting systems based on OGS and stilbene detectors were constructed and tested using a ^{252}Cf source. Stilbene and BC-501A exhibited excellent PSD performance, EJ-276D showed high fast-neutron detection efficiency, and OGS provided superior timing response. The OGS-based system successfully measured neutron double- and triple-coincidence events with and without lead shielding, whereas the stilbene-based system showed a marked reduction in coincidence events under unshielded conditions. These results indicate that combining PSD, neutron coincidence counting, and gamma-ray shielding enhances the extraction of correlated neutron signals in photonuclear NDA. The proposed OGS-based approach is a promising for active interrogation systems in nuclear security and safeguards.

Abstract

CEA Cadarache currently manages over 6,000 historical 870 L nuclear waste packages. To ensure long-term safety, French regulatory authorities require a precise characterization of each unit, specifically regarding structural integrity, fissile material mass and total activity of alpha emitters. However, the high density and volume of 870 L concrete waste packages result in significant signal attenuation, making standard passive gamma spectrometry or passive and active neutron measurements inefficient to assess the mass of nuclear materials. To maximize the signal-to-noise ratio, a specific Active Photon Interrogation (API) approach is developed inside the CINPHONIE irradiation bunker of CHICADE facility, at CEA IRESNE, Cadarache, France. This method makes use of inorganic BGO scintillators to measure high-energy delayed gamma rays from short-lived photofission products induced with a high-energy bremsstrahlung photon source, i.e., a 18 MeV LINAC. A Bayesian framework is applied to infer both the mass and the position of nuclear materials from angular acquisitions. This article is focused on testing API framework in the case where the source of the signal is located in a homogeneous environment. Based on the promising results presented here, future developments will focus on the heterogenous case.

Development and Performance Evaluation of a Four-Detector RMS in Compliance with IEC 60532 (#1540)

Dongam Yang, Sungho Lee

Korea Atomic Energy Research Institute (KAERI), Radiation Safety Management Division, Daejeon, South Korea

This work was supported by Korea Atomic Energy Research Institute (KAERI) R&D Program (No. 522430-26)

Abstract

Radiation monitoring systems (RMS) are essential for continuous radiation surveillance and rapid alarm generation in nuclear facilities. This paper presents the development and performance evaluation of a miniaturized Local Processing and Display Unit (LPDU)-based RMS designed to reduce installation space and radioactive waste generation while maintaining reliable monitoring performance. The developed RMS adopts a 1:4 architecture that enables a single LPDU to process and display signals from four independent detectors. The system was implemented using a Texas Instruments TMS2800137-based edge device and a Canberra G64IC detector. Firmware was developed to support pulse counting, EEPROM operation, RS-232/RS-485 communication, and real-time data processing. A dedicated communication protocol with Cyclic Redundancy Check (CRC) verification was also implemented to enhance data integrity. In addition, a Centered Significant Test (CST)-based adaptive filtering algorithm was embedded in the edge device to improve noise suppression and detector signal monitoring under field conditions. Performance verification tests were conducted in accordance with IEC 60532:2010 using a calibrated Cs-137 gamma radiation source. The developed RMS satisfied the acceptance criteria for linearity, statistical fluctuations, response time, and alarm response time and stability. The maximum linearity deviation was 2.1%, the coefficient of variation was 0.0203%, and all response times were below 6 s. These results demonstrate that the proposed RMS provides reliable radiation monitoring performance in a compact multi-detector configuration.

Abstract

Silicon photomultiplier (SiPM) based thermal neutron detectors have been developed at Oak Ridge National Laboratory for single crystal diffraction instruments. They have potential as good replacements for current 3He detectors on neutron reflectometers due to their high spatial resolution and fast scintillator decay time. The current software-implemented position fitting on these detectors is limited due to the processing required for the recursive least-squares algorithm. In this work, we present a fast method for determining neutron position that can be run on the Field-Programmable Gate Array (FPGA) chip that is already installed on the detector. This method compares the collected event data with pre-determined shapes stored on FPGA memory in parallel, and determines the one with the least linear error. Using this method for neutron positioning takes less time than the hardware defined dead time. Count-rate and spatial resolution results collected at the High-Flux Isotope Reactor are presented, with output count rates > 500 kcps achieved, an order of magnitude greater than the software fitting method.

Method for determining lithium ore's grade based on photoneutrons' lifetime measurement (#1637)

Minfeng Yu[1,2], Yigang Yang[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Tsinghua University, Key Laboratory of Particle & Radiation Imaging, Beijing, China

This research was supported by the Natural Science Foundation of Beijing, China (Grant No. L252023).

Abstract

Analysis of lithium ore grade is industrially significant for efficient lithium resource development and utilization, enabling improved production efficiency and reduced costs. Lithium has a large neutron absorption cross-section, and changes in lithium grade can affect the neutron lifetime, which is inversely proportional to the macroscopic absorption cross-section of ore. In this paper, a method for determining lithium grade through neutron lifetime measurements based on an e-LINAC driven photoneutron source is applied to the online analysis of lithium ore grade. Since lithium does not emit gamma rays upon neutron absorption, the neutron lifetime is measured from the time distribution of capture gamma rays induced by neutrons in the matrix elements of the medium. The feasibility of this approach has been demonstrated in experiments using various lithium nitrate solutions as simplified media. Meanwhile, the effect of neutron diffusion was investigated by simulations. The potential of neutron-induced prompt gamma analysis for reducing interference caused by variations in matrix composition is discussed. Further simulation studies and system design are in progress.

EJ309-Based Neutron–Photon Detection for Photoneutron Characterisation and High-Altitude Radiation Assessment (#1848)

Khalil Al Khouri[1], Mathis Bony[1], Valentin Blideanu[1], Benjamin Rapp[2]

[1] Université Paris-Saclay, Laboratoire National Henri Becquerel at CEA, Paris, France; [2] Université Paris-Saclay, IRFU at CEA, Paris, France

Abstract

This work presents an EJ309 organic liquid scintillator system for neutron–photon detection in mixed radiation fields. The performances achieved are illustrated through two complementary use cases. The first concern photoneutron production in pulsed high-energy photon fields generated by a TrueBeam medical electron LINAC and it has been used to characterise neutron–photon pulse-shape discrimination, integrated-charge observables, pile-up and saturation signatures, and the response of the acquisition chain under short intense irradiation pulses. This configuration simulates closely enough the energies involved in high-altitude cosmic-ray neutron production allowing the use of the previously qualified detection system to be used for neutron monitoring at the Jungfraujoch research station (Switzerland, at 3600 m), where the neutron field is mainly produced by atmospheric secondary cascades, including proton- and alphainduced spallation reactions. The detection set-up and analysis framework will be used to measure time-resolved neutron-like and photon-like event populations, pulse-shape discrimination distributions, and spectral observables over long acquisition periods. The work demonstrates the use of EJ309 scintillators for fast-neutron detection in controlled photoneutron fields and supports their application to natural high-altitude cosmic-ray environments, atmospheric radiation monitoring, and photoneutron studies relevant to intense high-energy photon fields.

Multimodal extension of the Feynman model for thermal neutron multiplicity counters (#1916)

Gabriel Chartier[1], Jonathan Dumazert[1], Benoit Laurent[1], Louis Cavallini[1], Marc Labalme[2]

[1] Commissariat à l'Énergie Atomique, DAM, DIF, Arpajon, France; [2] LPC Caen, Normandie Univ, ENSICAEN, UNICAEN, CNRS/IN2P3, Caen, France

Abstract
The point kinetics model can be extended to multiple regions or energy groups to account for system heterogeneities. This paper presents an extension of the Feynman-α technique in diverse measurement configurations relevant to nuclear safeguards. This extension is achieved by incorporating phase-type distributions into the heuristic derivation of the Feynman model. Phase-type distributions effectively capture the absorption times of finite-state Markov processes. The resulting expressions are specifically tailored to each experimental configuration. In a bare source configuration using an array of ^{3}He-filled proportional counters, the neutron decay exhibits bimodal behavior. When a supplementary reflector is added to the setup, a third term emerges in the expression, as expected. However, the shape of this additional term depends on the type of reflector, due to

assumptions in the system's transition matrix. When fitted to simulated datasets, these new models show the fundamental decay mode of the detector (approximately 70 μs) and are validated with a 95% confidence χ2 test.

Abstract
A two-stage Compton camera prototype was developed for compact gamma-ray imaging applications in medicine [1]. Each camera layer consists of four monolithic 14 × 14 × 25.4 mm^3 $LaBr_3$:Ce scintillation detector assemblies manufactured by CapeScint, each coupled to a single-channel silicon photomultiplier (SiPM) readout. This configuration does not provide intrinsic position sensitivity within individual crystals.
Detector performance was experimentally characterised and modelled using the TOPAS Monte Carlo toolkit, with validation performed against standard gamma-ray calibration sources [2]. Data acquisition was performed using a XIA PIXIE-16 fully digital signal processing system operating in list-mode, enabling event-by-event energy and timing extraction with digital pulse processing [3]. The detectors achieved an energy resolution of approximately 3.4% at 662 keV and a coincidence timing resolution of 988(17) ps.
Imaging performance was evaluated using a GBq ^{137}Cs source at multiple source-to-detector distances. Reconstructed experimental images were compared with validated simulations, with simulations yielding a full width at half maximum (FWHM) of 3.36(1) mm and an angular resolution measure (ARM) of 1.47(13)°.

Results demonstrate agreement between experiment and simulation, validating the modelling framework and supporting the feasibility of compact $LaBr_3$:Ce-based Compton camera systems for medical gamma-ray imaging applications.

Dosimetry and Beam-Condition Characterization of Mixed-Field Irradiation Positions at CERN CHARM (#2131)

Salvatore Fiore, Federico Ravotti, Salvatore Danzeca

CERN, Geneva, Switzerland

Abstract

Mixed-field irradiation facilities require accurate and traceable dosimetry to support the qualification of electronic components and systems for accelerator environments. This work presents an updated dosimetry and beam-condition characterization of the CERN High-energy AcceleRator Mixed-field facility (CHARM), focusing on the comparison of different irradiation positions and on the extension of the available test conditions to new high dose-rate and high fluence locations close to the target. The study combines active and passive dosimetry methods, including CERN RadMon radiation monitors, radiophotoluminescent glass dosimeters and alanine dosimeters, to evaluate Total Ionizing Dose and fluence-related quantities under representative operating conditions. Measurements acquired during commissioning are compared with data collected during user operation to assess the stability and reproducibility of the delivered radiation fields. In addition, the effect of upstream IRRAD samples on the residual beam reaching the CHARM target is investigated using the IRRAD beam position monitors and the multi-wire proportional chamber installed at the end of the T8 beam line. Variations in the upstream material configuration are shown to affect the transported beam properties, including divergence, with a measurable impact on the resulting mixed field. The combined dosimetry and beam instrumentation data are used to validate the new irradiation positions, compare independent dosimetry techniques and define operational reference conditions for CHARM tests. These results improve the traceability of dose and fluence delivery in mixed-field accelerator irradiation campaigns and support more robust interpretation of radiation effects tests performed at CHARM.

Abstract

Gamma-ray spectroscopy is a fundamental technique for identifying radioisotopes in safety-critical applications. However, in scenarios such as nuclear accidents, high-temperature and high-radiation environments severely degrade photomultiplier tube performance. Conventional temperature compensation systems face physical voltage limits, and prior deep-learning algorithms fail because they require preserved spectral shapes. To overcome these limitations, this study presents a comprehensive strategy to enhance detector stability. First, an active high-voltage control system mitigates initial temperature-induced gain loss. Because this hardware compensation eventually reaches its physical safety limits, the system integrates a deep learning (DL) technique – bidirectional long short-term memory network – to interpret residual spectral distortions, successfully achieving accurate multi-isotope quantification up to 185 °C. Second, to address radiation-induced damage localized within the photomultiplier tube, a targeted active thermal annealing protocol was applied. Following a 1.55 kGy cumulative gamma irradiation, detector output dropped to 23.5% of its baseline. Subsequent thermal annealing of the photomultiplier tube body at 145 °C successfully restored the output to 89.4%. Ultimately, this integration of hardware, software, and active recovery lays a foundation for robust radionuclide identification under concurrent high-temperature and high-radiation constraints.

Abstract

Large cargo scanning presents a unique challenge for national security. Container size limitations pose challenges to tomographic imaging. This work proposes a new stationary, limited angle tomographic transmission scanner geometry with a unique β/γ source utilizing a pair of fixed flat panel detectors, known as Gamma Tomography (GT). A Gate 10 simulation evaluates the imaging capabilities of the scanner and explores time-of-flight (TOF) and energy discrimination as electronic collimation methods to reduce scattered radiation and improve image quality. A 600 μm thin plastic scintillator sheet encasing 100mCi of ^{60}Co as a near detector locally captures nearly all emitted β particles without significant γ interactions, while a far detector panel of 2 cm thick LYSO crystals captures the ~1.25 MeV energy ^{60}Co γ photons. Both panels were simulated as 50x80 cm with a thin, 2 cm thick, multi-material test object consisting of water, aluminum, titanium, steel, and uranium in the center of the field of view. The same simulation dataset was reconstructed with/without two separate electronic collimation schemes: valid coincidences with a 100 keV energy window around the ^{60}Co photopeaks, and valid coincidences with a 100 ps time resolution. Despite the short acquisition time (18sec), reconstructed images are low noise, with all objects visible above background and distinguishable. The images show attenuation coefficient under-estimation, due to object scatter. TOF and energy discrimination underestimate μ values by 25.8% and 34.3% respectively, but a large dynamic range and very high SNR in μ value is achieved for all reconstructions (SNR-water: 46, SNR-Uranium: 1369). Using time information in lieu of energy allows events scattered in the detector to be used to improve image quality and SNR, but further investigation will include achievable time resolution, panel construction, and source geometry optimization.

A Large-Area Spectroscopic Alpha Imaging Detector for Dual-Isotope Imaging of ^{225}Ac and ^{213}Bi in Targeted Alpha Therapy (#2275)

Jong-Guk Kim, Byoung Soo Kim, Ilhan Lim, Kyo Chul Lee

Korea Institute of Radiological and Medical Sciences, Seoul, South Korea

Abstract

Alpha particle autoradiography is an emerging modality for mapping the biodistribution of alpha-emitting radionuclides in preclinical studies, supporting the development of radiopharmaceuticals for targeted alpha therapy (TAT). Considerable effort has been directed toward achieving high spatial resolution, with recent advances emphasizing single-event processing and energy-resolved detection to identify the nuclide of origin of individual alpha particles. Our previous work validated a spectrum decomposition method for dual-isotope imaging of ^{225}Ac and ^{213}Bi using a spectroscopic alpha imaging detector, confirming its feasibility with therapeutic amounts of ^{225}Ac. However, the active area of that system was constrained to 2.5 cm × 2.5 cm, limiting its applicability to small fields of view. To overcome this constraint and accommodate simultaneous imaging of multiple tissue sections or organs from larger animals, we developed a large-area spectroscopic alpha imaging detector with an active area of 5 cm × 5 cm, representing a fourfold increase over the prior system. The detector achieved an energy resolution of 4.3% FWHM at 5 MeV and a spatial resolution of approximately 600 μm, representing a substantial improvement over the prior system. Future work will include demonstration of dual-isotope spectral imaging of ^{225}Ac and ^{213}Bi to support preclinical TAT evaluations.

Abstract

Scintillator-on-fiber (SOF) detectors utilizing Liglass scintillators show strong potential for neutron flux monitoring in intense radiation environments due to their high radiation hardness and fast response. Previous studies have typically employed fragmented scintillators in SOF detectors due to the difficulty of μm-scale machining. In this work, Li-glass scintillators with well-defined dimensions (1×1×0.5 to 0.25×0.25×0.5 mm^3) were precisely fabricated using laser cutting, enabling a systematic investigation of the effect of scintillator size on neutron response linearity in an acceleratordriven neutron beam. With pulse-shape discrimination (PSD), the results show that neutron signals measured with scintillator sizes larger than 0.5×0.5×0.5 mm^3 become blurred in the P_{SP}-channel scatter plot due to gamma-ray contributions and pulse pile-up at an accelerator current of 250 μA. In contrast, the smallest scintillator (0.25×0.25×0.5 mm^3) maintains clear separation between neutron and gamma-ray signals. Analysis of the maximum shift error σ_m of the neutron peak centroid further indicates that this smallest scintillator effectively suppresses pileup, achieving σ_m = 0. In terms of linearity, scintillators with sizes below 0.75×0.75×0.5 mm^3 yield

coefficients of determination $R^2 > 0.99$ when processed using a two-dimensional fiducial cut, satisfying the requirements for neutron flux monitoring in boron neutron capture therapy (BNCT). These results demonstrate the feasibility of optimizing Li-glass scintillator size and volume in SOF detectors to achieve reliable neutron flux monitoring in BNCT applications.

Performance Evaluation of a DOI-Based Directional Radiation Monitoring System for Moving Radiation Source Tracking (#2334)

Yoon Soo Chung, Juwan Kang, Jiwon Ra, Yong Hyun Chung

Yonsei University, Radiation Convergence Engineering, Wonju, South Korea

Abstract

Radiation accident response requires real-time source-direction and radionuclide information. However, conventional systems are limited in simultaneously achieving radionuclide identification, direction estimation, 360° monitoring, real-time processing, and multiple-source detection. To address this, a directional radiation monitoring system (DRMS) using the depth-of-interaction (DOI) method was developed previously, and its feasibility for 360° monitoring and multiple-source detection was verified. This study evaluated the real-time direction detection performance of the developed DRMS under moving-source conditions. The DRMS consisted of a CsI(Tl) scintillator (1" diameter, 4" height), two photomultiplier tubes coupled to both ends, a cylindrical collimator with eight slots arranged in different directions, and an FPGA-based DAQ. The system calculated gamma-ray energy and DOI using the sum and ratio of the two PMT signals, respectively, and generated radiation distribution maps in real time based on the slot direction corresponding to the estimated DOI layer. Evaluation was conducted assuming an accident scenario in which a 5 TBq radiation source mounted on a vehicle moved at 40 km/h, 100 m from the system. To reproduce this in a laboratory, measurements used a 3.17 MBq ^{137}Cs source moved at 4.23 cm/min, 1 m from the system, under the same count-rate condition. Energy windows were applied to the data, and the nuclide was identified when counts within its window satisfied the criterion. A nuclide distribution map updated at fixed count intervals to reflect the real-time source position and an accumulated distribution map reflecting the total response were generated. The results confirmed that the system could visually reflect the position change and movement trajectory of a moving source. These results demonstrate the potential of the DOI-based DRMS for real-time source-direction monitoring in radiation accident response and mobile radiation detection.

Development of a Portable High-Gamma-Ray-resistant Alpha and Beta Dust Monitor (#2423)

Misaki Hirato

Japan Atomic Energy Agency, Plutonium Radiation Control Section Radiation Protection Department, Muramatsu, Tokai-Mura, Naka-gun, Japan

This work was supported by JAEA Nuclear Energy S&T and Human Resource Development Project Grant Number JPJA25P 25135771.

Abstract

Measuring the radioactivity concentrations of airborne dust is crucial for selecting appropriate protective equipment for radiation workers and assessing internal exposure of them. In this study, we aim to develop a portable dust monitor that can measure alpha and beta rays simultaneously without being affected by ambient gamma rays. For the development, we utilize the clothing contamination monitor, which has been successfully put into practical use in previous research.

We investigated whether it was possible to distinguish between alpha and beta rays based on their respective energy spectra by irradiation tests. The results showed that by setting appropriate regions of interest (ROIs), we were able to minimize the influence of gamma rays and successfully distinguish and measure alpha and beta rays.

Abstract

This work systematically characterizes how transistor geometry governs neutron displacement damage (DD)-induced degradation in silicon MOSFETs. A monolithic single-chip array integrating 1.8 V and 3.3 V NMOS/PMOS devices with seven channel widths and 1-, 5-, and 10-finger layouts was fabricated as the device under test, and a hierarchical 1 GHz multiplexing readout was developed to track 84 transistors in real time during irradiation at TRIUMF (10^6–10^{10} n/cm², five incremental steps, annealing monitored up to 40 days). For 1.8 V NMOS devices, the post-irradiation output-voltage shift scaled with channel width, while the threshold-voltage shift after 40-day annealing varied strongly with finger configuration at the same total channel width. These results indicate a strong dependence of DD-induced degradation on finger topology, beyond what channel-width scaling alone can explain, with 10-finger layouts exhibiting anomalous nonlinearity attributable to parasitic coupling and non-uniform damage.

Solid-State Large-Area Contamination Detector Using Lightlink™ technology for Contamination and clearance equipment (#2688)

Philippe Talent

Mirion Technologies, R&D, Lamanon, France

Abstract

This paper presents a solid-state detection technology designed to improve large-area surface contamination measurements and enable integration into contamination and clearance equipment or robotics.
The primary objective is to replace photomultiplier-based detectors with compact architecture using solid-state photosensors and embedded digital processing, while maintaining or improving detection performance.
The proposed detector consists of a 579cm² sensitive surface divided into two independent channels, each coupled to integrated electronics performing biasing, signal processing, self-test, and communication. A daisy-chain configuration was implemented to evaluate system scalability, allowing up to fifty detectors to operate

synchronously within a single network. Measurements demonstrate detection homogeneity better than plus or minus fifteen percent over the active area and typical hemispherical efficiencies up to forty-six percent for high-energy beta emitters. The acquisition architecture enables rapid readout compatible with moving platforms, with sampling rates reaching one hundred measurements per second for moderate network sizes.
Compared with legacy systems, the proposed solution significantly reduces mass while improving robustness and insensitivity to magnetic fields and eliminates the need for complex external electronics. These results confirm that solid-state based large-area detectors can achieve high-performance contamination monitoring while enabling modular, scalable, and easily deployable systems. The approach opens new perspectives for robotic applications and large-area inspection in nuclear environments.

Performance Evaluation of the SNIPER-GN Portable Gamma–Neutron Detection System (#2692)

Paola Garosi, **Fabio Davolio**, Cristiana Del Bene, Giacomo Mangiagalli, Massimo Morichi, Carlo Uguccioni

CAEN S.p.A., Viareggio, Italy

Abstract
This work presents the experimental validation of SNIPER-GN, a portable gamma–neutron detection and identification system whose core innovation is a patented neutron identification algorithm (U.S. Patent No. 11835477). The algorithm enables robust and reliable neutron identification under challenging operational conditions, including shielding, moderation effects, and intense masking gamma radiation fields, representing a significant advancement over conventional detection approaches. The system integrates a high-efficiency gamma–neutron counter with a mid–high-resolution scintillation detector for rapid localization and characterization of radioactive threats, including Special Nuclear Material. The patented algorithm constitutes the enabling technology of the system and was the primary focus of the experimental verification campaign. Extensive performance testing was conducted in several international laboratories using calibrated sources under both static and dynamic measurement conditions. The system successfully identified neutron-emitting sources down to approximately 1 count per second with background levels below 0.1 counts per second, while gamma identification remained stable above 60 net counts per second over background. Tests employing polyethylene and lead shielding demonstrated identification success rates up to 100% depending on source geometry and activity, confirming robustness in realistic scenarios. Dynamic tests compliant with ANSI N42.53 confirmed reliable alarm performance for moving sources. Additional validation for field applications, such as rapid analysis of air-sampler filters and iodine cartridges for post-fallout monitoring, showed astonishing minimum detectable activities within measurement times shorter than five minutes.
Overall, these results validate the patented technology and demonstrate the suitability of SNIPER-GN for homeland security, emergency response, and radiological field deployment scenarios.

Abstract

Neutron imaging plays an irreplaceable role in the restoration of cultural relics and the study of lithium battery charging and discharging behaviors. The performance of neutron imaging detector directly determines the imaging quality. A cold neutron imaging detector based on a structured $^{10}B_2O_3$-ZnS:Cu scintillation screen was developed and tested at China Mianyang Research Reactor (CMRR) Cold Neutron Radiography Facility. The structured screen was made of glass microchannel plate (MCP), B_2O_3, ZnS:Cu and UV-curable binders. The refractive index contrast between the MCP (1.5) and the UV curable adhesive(1.62) leads to total internal reflection, thereby forming a light confinement structure. The spatial resolution was measured to be about 33μm with a Siemens Star Chart, and the cold neutron absorption efficiency was measured to be 24.4%

Revealing Disorder Faster: Detector Upgrades for SANDALS-II (#2826)

Sarah E. Mann, **Sarah E. Mann**, Nigel J. Rhodes, Nigel J. Rhodes, Erik M. Schooneveld, Erik M. Schooneveld, Giacomo Mauri, Giacomo Mauri, Jack Day, Jack Day, Oliver L.G. Alderman, Oliver L.G. Alderman, Terri-Louise Hughes, Terri-Louise Hughes, Daniel T. Bowron, Daniel T. Bowron, G. Jeff Sykora, G. Jeff Sykora

STFC, ISIS, Harwell Campus, UK

Abstract

SANDALS-II is an instrument being developed at the ISIS Neutron and Muon Source as a next generation diffractometer for the study of amorphous and liquid materials. This upgrade will deliver count rates up to 11 times

higher than the existing SANDALS instrument and will significantly expand its scientific capabilities. This work focuses on developments of a large area scintillator detector that are essential for achieving enhanced performance. Scintillation detectors for SANDALS-II will cover a solid angle of 0.67Ω, 2.4 times greater detector coverage than the current instrument. These detectors are required to have high efficiency, particularly at higher neutron energies (short wavelengths), which is achieved using a unique design employing tiles made from alternating layers of glass and scintillator. Scintillator and glass options are explored to optimise detector and instrument performance. Different low Li and B content glasses were tested to determine the most suitable option for the instrument that provides good neutron transmission while maintaining affordability. The ratio of ZnS:Ag to ^{6}LiF in the scintillator will be altered from 4:1 to 2:1 to enhance neutron absorption and therefore detection efficiency. At 30eV (0.05Å) this offers a 60% improvement in detection efficiency. The applicability of low-afterglow scintillator, ZnO:Zn/^{6}LiF, for use in SANDALS-II is also explored. ZnO:Zn/^{6}LiF is shown to offer a 2x increase in count rate capability over ZnS:Ag/^{6}LiF, but a 6% lower neutron detection efficiency. As the reduction in efficiency using ZnO:Zn/^{6}LiF is modest, this alternative scintillator offers a viable solution for the high count rate regions of SANDALS-II. With optimised glass and scintillator selection, the performance required for the upgraded instrument can be delivered. This will enable faster measurements, smaller sample studies, and time resolved experiments, making SANDALS-II a world leading disordered material neutron diffractometer.

This work was supported by the Technology development Program(RS-2024-00469068) funded by the Ministry of SMEs and Startups(MSS, Korea)

Abstract

This study evaluated the performance of a $LaBr_3$(Ce) scintillation detector for elemental identification and mass-fraction estimation in a thermal-neutron-based prompt gamma-ray neutron activation analysis (PGNAA) system, in comparison with a conventional NaI(Tl) detector. PGNAA spectra were acquired at the Four-Circle Diffractometer (FCD) beamline of the HANARO research reactor at the Korea Atomic Energy Research Institute. The measured samples included pure Mn, Fe, Co, and Ni samples; binary Fe–Mn, Fe–Co, and Fe–Ni mixtures; and ternary NCM622 and NCM811 samples simulating spent lithium-ion battery cathode materials. Elemental identification was performed using Gaussian-derivative-convolution-based peak detection, SNIP baseline correction, and Currie-criterion-based significance testing. Mass fractions were estimated using region-of-interest-based weighted non-

negative least squares (WNNLS) with attenuation-integration correction. $LaBr_3(Ce)$ produced higher Z-scores, smaller energy-matching errors, and more stable characteristic peak combinations in mixed samples than NaI(Tl). For NCM622 and NCM811, $LaBr_3(Ce)$ achieved mean absolute errors of 4.3 and 1.9 percentage points, respectively, while also providing higher R^2 values for spectral-shape reproduction. These results indicate that $LaBr_3(Ce)$ offers improved peak separation and compositional estimation capability for nondestructive analysis of complex industrial samples, including spent lithium-ion battery cathode materials.

Abstract
This work presents a novel neutron detector concept aiming to provide detection efficiency and background levels equivalent to conventional ^{3}He-based detectors, whilst boosting the maximum counting rate by several orders of magnitude. The detector retains the form-factor of a standard ^{3}He tube and uses the same working gas mixture of ^{3}He with admixture of CF_4 as the stopping gas. The key innovation is a fast optical readout of CF_4 prompt scintillation light using silicon photomultiplier (SiPM) sensors. The target performance is a detection efficiency equivalent to that of a standard ^{3}He tube under identical gas filling conditions, gamma sensitivity below 10^{-6}, and a maximum counting rate of 2 MHz/pixel, orders of magnitude improvement over existing detectors. The fast emission of CF_4 scintillation light is the enabling factor for achieving ultra-high counting rates. CF_4 exhibits a considerable photon yield, with one scintillation band in the UV and another in the visible region of the spectrum, with several thousands of photons emitted per neutron event. The efficient collection of light by the SiPMs constitutes a critical design parameter, addressed in this study through Monte Carlo optimization. The gas mixture composition is optimised to maximise the scintillation yield, and a gas purification system can be integrated into the detector to ensure long-term stability. The first experimental results of a detector prototype characterisation on a neutron beamline at the Institut Laue-Langevin (ILL) will be presented.

Abstract

The response of Timepix detectors with different sensors (Si, SiC, GaAs, CdTe) to thermal, slow, and fast neutrons is studied. Measurements at tunable mono-energetic neutron fields are compared and analyzed with nuclear-reaction models and numerical calculations. Specific radiation-type and sensor-material interaction neutron detection channels are derived for each detector-sensor configuration. These results serve to better and more completely process radiation data acquired with these detectors. Combining multi-detector measurements expands and enhances the resolving power of field decomposition.

Characterization of 3D ultra-thin silicon-based thermal neutron detectors (#3088)

Felipe Zamorano, Iván Lopez, Martín Pérez, Javier Bravo, Celeste Fleta, Consuelo Guardiola

Institute of Microelectronics of Barcelona, Barcelona, Spain

This project has received funding from the Consejo de Seguridad Nuclear (CSN) under the project Subvenciones 2022 SUB-08.

Abstract

Neutron contamination in advanced radiotherapy and other mixed radiation environments has become an increasing concern due to the limitations of conventional neutron detectors under intense gamma background conditions. In this work, ultra-thin 3D silicon neutron detectors specifically designed for operation in mixed radiation fields were experimentally characterized under thermal and high-energy irradiation conditions. The detectors, consisting of 20 µm-thick silicon sensors paired with ^{6}LiF neutron conversion layers, were tested at the FANT thermal neutron facility and at the CERN High-Energy Reference Field (CERF). Measurements included reproducibility, angular dependence, bias voltage operation, and discrimination threshold effects using a low-voltage FPGA-based readout system. The results showed stable operation under mixed radiation fields, moderate angular dependence, and strong dependence of the response on detector bias and discrimination threshold. The ultra-thin detector architecture enabled high gamma rejection capability, enabling reliable neutron detection under intense photon background conditions. These results demonstrate the suitability of 3D ultra-thin silicon detectors for compact real-time neutron monitoring in radiation protection and medical applications.

A Full Rank Pileup Deconvolution Scheme Suitable for Calorimeter Online Trigger Primitive Generation (#1091)

Jinyuan Wu

Fermi National Accelerator Laboratory, Batavia, USA

This manuscript has been authored by Fermi Forward Discovery Group, LLC under Contract No. 89243024CSC000002 with the U.S. Department of Energy, Office of Science, Office of High Energy Physics.

Abstract

In this document, a pileup deconvolution scheme not relying on any mathematics guessing is presented. In high energy physics experiment, as the luminosity increases, pile-up issues on detectors such as calorimeters become non-negligible. Deconvolution approaches developed for data taken from DAQ systems are usually rank-deficient or underdetermined, having less equations than unknowns, even with the ADC values from multiple beam crossings are collected. These deconvolution approaches need mathematic pre-assumptions such as Sparse Representation. For online computation tasks such as for trigger primitive creation, signal availability is significantly different as in offline data analysis stage, and therefore, it is possible to use different (yet simpler) algorithms. In this situation, number of ADC values of the calorimeter outputs is the same as the number of beam crossings (or 4 times number of beam crossings, depending on the ADC sampling rate), and therefore, the number of equations can be arranged to be the same as number of unknowns. This way, a determined deconvolution scheme with a full-rank squared convolution (and deconvolution) matrix becomes possible. The robustness of deconvolution over long time windows is also studied in this paper.

This work was sponsored by the Office of Naval Research (ONR) as part of 6.1 funding.

Abstract
The Neutron Radiation Detection Instrument-1A (NeRDI-1A) is a technology demonstration payload on the International Space Station (ISS) as part of the Department of Defense Space Test Program (STP) mission STP-H9. The primary objective of NeRDI-1A is to space-qualify two detector technologies: a dual-mode gamma-neutron scintillator (Thallium-doped Cesium Lithium Yttrium Chloride, Tl_2LiYCl_6:Ce, or TLYC) and Domino microstructured semiconductor neutron detectors (MSNDs). The full NeRDI-1A suite includes a TLYC detector, three Domino MSNDs with varying moderation, and an EJ-270 plastic scintillator. This work focuses on the TLYC detector within NeRDI-1A. Here we present an analysis of the TLYC detector's response within distinct orbital regions--including the auroral regions and the South Atlantic Anomaly--during a period of minimal solar variability. We also present the evolution of the TLYC detector's performance over its operational lifetime.

Abstract
The Assessing Lunar Ion-Generated Neutrons (ALIGN) payload is an advanced spectrometer developed to characterize the lunar radiation environment during the Chang'E-8 mission. Designed to operate within a stringent mass allocation of 4.8 kg and optimized for low electrical consumption, the payload features a highly integrated coincidence telescope statically oriented at -30 degrees from the horizontal. This presentation details the

instrumental architecture and multi-particle detection methodologies of the payload. The detector array comprises Double-Sided Silicon Strip Detectors (DSSDs), an EJ-254 boron-loaded plastic scintillator, and a primary CLYC calorimeter, all enveloped by an active BC-408 plastic scintillator veto. The system employs the Δ[if gte msEquation 12]><m:oMath><span style='font-size:12.0pt;mso-bidi-font-size:15.0pt;line-height:115%;font-family: "Cambria Math",serif;mso-fareast-font-family:DengXian;mso-fareast-theme-font: minor-fareast;mso-bidi-font-family:"Cordia New";mso-bidi-theme-font:minor-bidi; mso-ansi-language:EN-US;mso-fareast-language:ZH-CN;mso-bidi-language:TH'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="p"/></m:rPr>Δ</m:r></m:oMath><![endif][if gte vml 1]><v:shape id="_x0000_i1025" type="#_x0000_t75" style='width:7.2pt;height:16.2pt'> <v:imagedata src="file:///C:/Users/Admin/AppData/Local/Packages/oice_16_974fa576_32c1d314_c6d/AC/Temp/msohtmlclip1/01/clip_image003.png" o:title="" chromakey="white"/></v:shape><![endif]E-E technique—correlating initial energy loss in the DSSD transmission trackers with total energy deposited in the scintillators—to separate upward-moving albedo protons (20–140 MeV) from background electrons. Concurrently, intrinsic Pulse Shape Discrimination (PSD) within the CLYC crystal is utilized to accurately separate epithermal neutrons from gamma-ray interactions. To achieve definitive particle identification within these strict size, weight, and power constraints, a dedicated onboard FPGA executes priority-based signal processing. Geant4 simulations evaluated the instrument's overall geometric acceptance as a function of incident kinetic energy. By combining these advanced onboard logic techniques with a streamlined composite radiation shield, structural design is expected to successfully isolate lunar albedo signals from localized lander interference while fully satisfying the mission's strict engineering constraints.

Cluster Size Simulation to Predict LHCb Upgrade I VELO Performance

(#1945)

Sean J. Williams[1], Emma Buchanan[2], David Friday[3], Jaap Velthuis[1], On behalf of the LHCb VELO group

[1] University of Bristol, H.H. Wills Physics Laboratory, Bristol, UK; [2] University of Edinburgh, School of Physics and Astronomy, Edinburgh, UK; [3] University of Manchester, Department of Physics and Astronomy, Manchester, UK

Abstract

The LHCb experiment recently underwent an extensive upgrade program to allow operation at higher luminosities. The VErtex LOcator (VELO) was redesigned to a hybrid pixel layout with 130nm CMOS technology. As a result of the upgrade, the VELO will be exposed to an extreme radiation environment – over an order of magnitude greater than before. At the end of its lifetime, the innermost regions are expected to be exposed to $8x10^{15}$MeV n_{eq} cm^{-2} [1]. Previous analysis of bias voltage scans (presented at IEEE Yokohama, 2025) has shown the VELO is at risk of exceeding the maximum 1000V bias voltage limit to remain at operational performance. Here, we present a data-

driven simulation of clusters in the VELO, to predict the performance at the end of its lifetime. Extensive validation of the simulation to testbeam data is performed, with angle and bias voltage scans showing very good agreement. Furthermore, charge sharing via diffusion in the simulation is authenticated with the charge collection vs intra-pixel hit position for size 2 clusters. Excellent agreement is seen. Comparison to Run III data is presented, showing good correspondence with the installed sensor. Extrapolations of the sensor performance at $8x10^{15}$MeV n_{eq} cm^{-2} are performed. Preliminary results estimate the hit efficiency to be 89.41±0.14\% and the spatial resolution to be 19.98±0.37μm (a 19.8% increase from non-irradiated). These results highlight the need to make use of beneficial annealing for the rest of the sensor lifetime, to ensure performance remains as good as possible.

NSS-01-285

Design of Readout Electronics for a CdZnTe Detector Prototype for Polar-orbiting Solar Hard X-ray Imaging Telescope (#2200)

ZeKun Wang[1,2], Shen Wang[1], Zhe Zhang[1]

[1] Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China; [2] University of Science and Technology of China, School of Astronomy and Space Science, Nanjing, China

Abstract

To support the X-ray Imaging Telescope (XIT) onboard China's Solar Polar Orbiting Observatory, which aims to perform the first-ever imaging of the Sun polar regions and study high-energy processes in solar eruptions, we have developed a prototype readout electronics system for a CdZnTe hard X-ray detector. The system consists of a 2 mm thick CdZnTe detector with an effective area of 15 × 15 mm² segmented into four strip electrodes with switchable area ratios, a front-end electronics board employing the IDE4281 charge-sensitive preamplifier ASIC, and a FPGA-based data acquisition unit with integrated calibration and high-voltage supply. The IDE4281 chip provides 12 channels with programmable shaping times, self-triggering, and peak-hold outputs. In the readout prototype, the equivalent noise charge after common-mode noise subtraction ranges from 149 to 189 e^- across all channels. Using a ^{241}Am radioactive source, the detector demonstrates a full-width at half-maximum energy resolution of 4.92 keV at 59.5 keV, fulfilling the scientific requirement of better than 5 keV at that energy. These results validate the prototype design and establish the basis for the forthcoming X-ray imaging telescope instrument.

Abstract

Since its installation, the Timepix3 detector network has demonstrated utility within the ATLAS cavern by providing radiation field measurements and relative luminosity monitoring. This work evaluates the performance and internal stability of the network during the entire LHC Run 3. To ensure robust monitoring and assess systematic uncertainties, three distinct algorithms were evaluated and compared: cluster counting, thermal neutron counting, and heavy and straight track counting.

Clean signal was achieved by identifying and masking noisy pixels and by modeling and subtracting background activation by a recursive growth and decay model. Internal consistency was verified through both short-term (intra-fill) and long-term (yearly) stability analyses across detectors situated at different distances from the interaction point. The presented results demonstrate that the distributed Timepix3 network provides a stable and robust relative luminosity measurement, complementing primary ATLAS luminometers during Run 3.

Abstract

The LHCb Upgrade II, planned for Run5, will operate at a substantially higher luminosity than previous runs, motivating dedicated FLUKA simulations of the resulting mixed-field radiation environment. This work addresses the impact of two major changes: the upgraded Electromagnetic Calorimeter, referred to as PicoCal, and the shielding of the Muon System. The increased fraction of high-density material in the PicoCal central modules modifies shower development and neutron production, while additional shielding is required to preserve Muon System performance. All comparisons are made with respect to the same Run4 reference configuration without additional Muon System shielding. Two Muon System shielding solutions are evaluated: i) replacement of the Hadronic Calorimeter by an iron-and-concrete shield with borated-polyethylene plates upstream and downstream, and ii) retention of the present Hadronic Calorimeter followed by a ductile cast iron, borated-polyethylene and steel wall. The simulations show increased local neutron production around the PicoCal central modules, while the existing polyethylene-and-boron shield upstream of the calorimeter limits the impact on upstream sub-detectors. For the Muon System, both shielding strategies reduce the charged-particle fluence relevant for detector performance, with different spatial and particle-composition trade-offs. These results support the optimization of the LHCb Upgrade II layout and illustrate the role of detector radiation studies for shielding design in mixed-field high-energy physics environments.

Timing properties of the FARCOS detection system (#2838)

Andrea Castoldi[1,2], **Chiara Guazzoni**[1,2], Andrea Mason[1,2], Mattia Pozzi[1,2], Riccardo Zambolo[1,2], on behalf of the fARCOS collaboration

[1] Politecnico di Milano and INFN, Dipartimento di Elettronica, Informazione e Bioingegneria, Milano, Italy; [2] INFN, Sezione di Milano, Milano, Italy

Abstract

FARCOS is a Femtoscope Array for Correlation and Spectroscopy designed to perform studies of two- and multi-particle and Intermediate Mass Fragments (IMFs) correlations in heavy-ion collisions at Fermi energies with stable and radioactive beams. The FARCOS system is a modular assembly of up to 20 telescopes to be used in combination with 4π detectors like the CHIMERA multidetector. Each telescope features two Silicon detection layers (32 + 32 channels Double Side Silicon Strip Detectors 300μm and 1500μm thick and a third calorimetric stage, made of four truncated pyramidal CsI(Tl) crystals arranged in a 2 x 2 matrix). Particular care has been posed in the design of the frontend electronics for the different stages. For the first time we performed a detailed qualification of the timing properties of the FARCOS frontend electronics and of the different detection stages. The achievable resolution was optimized thanks to an accurate analysis of the waveform shape. The remarkable time resolution measured at zero pf capacitive input load, with the FARCOS frontend electronics, below 100 ps rms at 1.1 MeV injected charge on the 100 MeV full-scale energy range, thanks to the excellent energy resolution below 15 keV FWHM paves the way to widen the range of experiments in which the FARCOS system will be applied. The measured time resolution improves to 25 ps rms at 5 MeV injected charge. The selectable gain factor allows the extension of the full-scale energy range up to a gain factor of 0.5mV/MeV over the full-scale range of 1.1V, with a small compromise on the time resolution, translating in a dynamic range of more than 15bits. The INL keeps below 0.5% over the full dynamic range. The timing performance of the Silicon layers of the FARCOS telescopes was then qualified with a near-infrared pulsed laser system and with alpha particles. This contribution presents the results of this qualification together with some highlights of the recent applications of the FARCOS telescopes.

Thermal and In Situ annealing tests for SiPM radiation damage mitigation (#2917)

Suomi Bez Baruah[1,2], Maria S. Ruzzarin[1], Fabio Acerbi[1], Alberto Gola[1]

[1] *Fondazione Bruno Kessler, CRS, Trento, Italy;* [2] *University of Trento, Physics, Trento, Italy*

National PhD Program in Space Science and Technology (University of Trento)

Abstract

Silicon Photomultipliers (SiPMs) are solid-state photodetectors increasingly employed in astrophysics and space missions due to their high photon detection efficiency (PDE), compactness, insensitivity to magnetic fields, and operation at relatively low bias voltages. However, exposure to radiation, through both Ionizing Energy Loss (IEL) and Non-Ionizing Energy Loss (NIEL) effects, can degrade their key performance parameters.

To mitigate radiation-induced damage, annealing strategies have been explored. This work presents the results of two annealing tests performed on FBK SiPMs, after x-ray irradiation and proton irradiation, highlighting their respective advantages and limitations: (1) thermal annealing, involves storing the devices in a climatic chamber without active heating, while periodically performing electrical measurements to track recovery over time. (2) In-situ current annealing progressively increases the SiPM bias current to induce self-heating via resistive effects. Electrical measurements have been done after each step, and a thermocamera have been used to monitor device temperature.

Axial Reactivity Profile Measurement of Polaris Using CR-39 Nuclear Track Detectors (#2958)

Sara Alawabdeh, Perry Young, Nate Kaneshige, Wolfgang Hennig, Daniel Cech, John Peterson, Ron Grazioso, Michael Y. Hua

Helion Energy, Nuclear Diagnostics, Everett, USA

Abstract

This work presents the measurement of the axial neutron emission profile of the Polaris field-reversed configuration (FRC) fusion machine using CR-39 solid-state nuclear track detectors (SSNTDs). Passive detectors were deployed at multiple axial positions along the Polaris compression section, accumulating neutron-induced proton recoil tracks over several pulses of moderate yield, sufficiently low to resolve tracks. Chemical etching in 6M NaOH at 85°C for 2.5 hours revealed latent damage tracks, which were analyzed using a custom Python-based image processing pipeline incorporating a trained Random Forest classifier achieving 94.1% ± 2.2% cross-validation accuracy in neutron track identification. The resulting axial track density profile is symmetric and centrally peaked, in agreement with MCNP-simulated neutron dose distributions for a thermonuclear DT fusion source confined within the FRC plasmoid. The absence of asymmetric structure - characteristic of beam-target dominated reactions - provides compelling experimental evidence of spatially confined thermonuclear fusion on Polaris. This represents the first deployment of CR-39 diagnostics for reactivity profiling on a pulsed FRC machine and establishes passive track detectors as an effective tool for fusion burn characterization.

On-detector Electronics for the ATLAS Liquid Argon Calorimeter Phase-II Upgrade at the High-Luminosity LHC (#2989)

Emmanuel Josue Molina Gonzalez[2], **Nikiforos Nikiforou**[1], On behalf of the ATLAS Collaboration

[1] CERN, Geneve, Switzerland; [2] Université Paris-Saclay, IRFU, CEA, PAris, France

Abstract

The ATLAS Liquid Argon (LAr) calorimeter readout electronics are being upgraded for operation at the High-Luminosity Large Hadron Collider (HL-LHC), where up to 200 proton-proton interactions per bunch crossing will significantly increase detector occupancy, trigger rates, and radiation levels. While the calorimeter detectors themselves remain unchanged, the complete readout electronics chain is being replaced. The upgraded on-detector electronics readout system continuously amplifies, shapes, digitizes, and transmits calorimeter signals from approximately 182000 channels at the 40 MHz bunch-crossing rate. The new Front-End Boards (FEB2) integrate custom radiation-hard ASICs including the ALFE2 preamplifier/shaper, the COLUTA analog-to-digital converter, and lpGBT optical communication devices. Prototype boards and ASICs have been developed and extensively tested in laboratory and integration environments. This contribution presents the architecture, development status, and recent performance results of the Phase-II front-end electronics for the ATLAS LAr calorimeter.

Airborne Measurement of Terrestrial Gamma-Ray Flashes with the High Elevation Radiation Array (#2287)

Juan J. Manfredi[1], Jeffrey M. Chaffin[2,1], Vaun Clagett[1], Michael Rynders[1], Jacob Weinberg[1], William Erwin[3]

[1] Air Force Institute of Technology, Department of Engineering Physics, Wright-Patterson AFB, USA; [2] California Polytechnic State University, San Luis Obispo, Physics Department, San Luis Obispo, USA; [3] Air Force Research Laboratory, 711th Human Performance Wing, Wright-Patterson AFB, USA

Abstract

This study investigates the unique high-energy radiation environment of thunderstorms, focusing on terrestrial gamma-ray flashes (TGFs). Led by the Air Force Institute of Technology, the United States Air Force School of Aerospace Medicine, and the Air Force Research Laboratory, this effort deploys custom-built High Elevation Radiation Array (HERA) instruments aboard ten WC-130J “Hurricane Hunter” aircraft. These planes fly into hurricanes and tropical storms for the purpose of measuring weather data, potentially bringing them into proximity of TGF radiation. Each HERA unit contains a sodium iodide scintillator, a plastic scintillator, and associated data acquisition hardware. HERA represents the largest airborne campaign to date for near-source TGF observations and aims to improve understanding of TGF mechanisms, occurrence rates, and associated radiation risks to aircrew and equipment. All HERA detectors have been installed on aircraft and will collect data during the full 2026 Atlantic hurricane season.

Systematic X-ray irradiations of a back illuminated, HPGe, microstrip sensor. (#1420)

Daniel Thacker, Marcello Borri, Matthew Buckland, William Helsby, Andrew Hill, Konrad Sutowski

UKRI - Science & Technology Facilities Council, Technology Department, Warrington, UK

The authors would like to acknowledge the UKRI-STFC for funding the X-ray irradiations facility (ST X004837-1), and the UKRI-STFC Centre for Instrumentation for funding R&D on HPGe sensors.

Abstract

Back illuminated, HPGe, microstrip sensors are operated in the cryogenic detector system called XH. XH enables the collection of energy dispersive X-ray absorption spectra to investigate near-instantaneous structural variations in experimental samples. XH detects the transmitted radiation of a bright, single flash of X-rays that is delayed with respect to a laser pulse, which also hits the sample and creates an excited state of matter. Each strip in the HPGe sensor detects the intensity of a spectral component ($\Delta E \sim 1.5$ eV) of the transmitted, dispersed polychromatic beam, which has a typical bandwidth of ~1 keV. The HPGe sensor can be exposed to beam intensities as high as 1×10^{13} ph/mm^2/s from polychromatic beams with a central energy in the range ~5 keV to ~25keV. The operation in this radiation harsh condition benefits from a systematic irradiation campaign to investigate ageing effects created by Total Ionising Dose (TID). The TID effects on the HPGe sensor are mitigated by design by adopting a back illumination approach in order to shield the strip contacts, and by the selection of a proprietary, commercial lithographic process. XH was irradiated at the X-ray Irradiation Facility at Daresbury Laboratory (UK). The 1024 strip sensor was repeatedly exposed to X-rays in finite time steps. Total leakage and strip currents were monitored regularly with X-rays on and off. The X-ray peak energy was limited to 20 keV, which was fully absorbed in the 1.5 mm thick HPGe sensor. This protected the strip contacts from radiation. Beam collimation within the active area of the HPGe sensor showed a steady performance, which was immune from TID. Evidence of deterioration in surface leakage current was measured when the beam was hitting the sensor edge and its supporting PCB.

This research used resources of the National Synchrotron Light Source II, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Brookhaven National Laboratory under Contract No. DE-SC0012704.

Abstract

White beam Laue diffraction is well-known as a means to orient single-crystal samples, but its use as a structure-determining tool is less exploited. One of the difficulties with the method is its incomplete measurement of the diffraction vector. Only its direction can be determined, but not its length, since conventional instrumentation does not provide the diffracted beam energy. In this paper we propose to use a high-resolution energy resolving detector to provide that information, together with NSLS-II's HEX beamline, which has a spectral range up to 200keV. We have developed a series of microstrip germanium detectors, and present here some measurements using one of them together with a horizontal aperture to emulate a 192 x 1 pixel detector with 250 micrometer pixels. By scanning this device in one dimension we could simulate a 2-dimensional detector with good energy resolution,. We have further designed and built a custom detector for this purpose, which has 192x2 pixels, each 250 x 250 micrometers, and so does not need the aperture, and which requires half the number of measurements. Data collected with these detectors will be presented.

Abstract

A fully digital readout architecture is described for high-throughput X-ray spectroscopy with silicon drift detectors (SDDs). The core challenge is the large-amplitude voltage ramp produced by transistor reset preamplifiers, which conventionally prevents direct digitization at spectroscopic resolution. In this work, sampling the preamplifier output with a 20-bit SAR ADC achieves a dynamic range exceeding 10^6, eliminating any analog conditioning stage upstream of the digitizer.

Throughput is sustained by combining four converters in a time-interleaved scheme, yielding an aggregate sampling rate of 160 Msps. A Zynq SoC provides the processing backbone, performing inter-channel timing alignment, gain equalization, and concurrent execution of the signal processing pipelines.

Two energy estimation algorithms run in parallel on the digitised data: a ramp-corrected trapezoidal filter and a model-based least-squares fitter that uses linear regression over the full inter-event sample record, remaining accurate even when pulse separation shrinks to sub-microsecond intervals. Experimental characterisation with ARDESIA multi-pixel SDD arrays and KETEK single-pixel detectors yields an energy resolution of 120.7 eV FWHM at low rate, 150 eV at 1 Mcps, and 180 eV at 2 Mcps, with live time exceeding 90% throughout.

NSS-01-307

High-resolution Germanium Detector system for Fluorescence-Mode X-ray Absorption Spectroscopy (#2626)

Abdul K. Rumaiz[1], Francesca Capocasa[2], Anthony J. Kuczewski[1], Giovanni Pinaroli[2], Thomas Krings[3], Bruce Ravel[4], David P. Siddons[1]

[1] Brookhaven National Laboratory, NSLS II, Upton, USA; [2] Brookhaven National Laboratory, Instrumentation Department, Upton, USA; [3] Forschungszentrum, Jülich, Germany; [4] National Institute of Standards and Technology, Gaithersburg, USA

Abstract

Fluorescence-mode X-ray Absorption Spectroscopy (XAS) at high photon energies require detectors with both high stopping power and excellent energy resolution to measure weak element-specific fluorescence signals. Conventional silicon-based detectors suffer from poor absorption efficiency above ~20 keV, while most high-Z semiconductor materials such as cadmium telluride (CdTe), cadmium zinc telluride (CZT), and gallium arsenide (GaAs) have largely been developed for imaging applications with comparatively limited spectroscopic performance. In contrast, Germanium combines excellent stopping power with superior intrinsic energy resolution owing to its low Fano factor and favorable charge transport properties, making it particularly attractive for spectroscopy in the 15-100 keV range. Here we report the development, fabrication, and characterization of Gepta-EX, a compact multi-channel high-purity germanium (HPGe) detector system designed for fluorescence-mode XAS. Gepta-EX incorporates a monolithic seven-channel HPGe pixel array integrated with low-noise CUBE charge-sensitive preamplifiers inside a thermally isolated compact cryostat operating near 90K. The detector achieves energy resolutions of 218 eV at 5.9 keV using an ^{55}Fe source and 373 eV at 59.5 keV using an ^{241}Am source, with uniform response across all channels. By avoiding the escape-peak interference commonly associated with silicon detectors while maintaining stable high-resolution performance at elevated X-ray energies, Gepta-EX provides a powerful platform for high-energy X-ray spectroscopy and fluorescence-mode XAS applications.

NSS-01-309

Visualization of beta-emitting nuclides in water using a CCD camera and CaF_2 scintillator (#1462)

Yuki Morishita[1], Marina Kanno[2]

[1] Japan Atomic Energy Agency, Collaborative Laboratories for Advanced Decommissioning Science (CLADS), Futaba County, Japan; [2] PESCO Co., Ltd., Tokyo, Japan

Abstract

At nuclear facilities such as decommissioning sites and reprocessing plants, continuous monitoring of radioactive liquid waste is essential to prevent the spread of contamination. While gamma-emitting radionuclides can be detected relatively easily using gamma-ray detectors, radionuclides emitting only alpha or beta radiation are difficult to measure remotely because these particles are strongly absorbed in water. Conventional liquid scintillation counting requires sample collection and pretreatment, making real-time monitoring difficult. In this study, a real-time visualization method for beta-emitting nuclides in water was developed using a calcium fluoride (CaF_2) scintillator and an Electron Multiplying CCD (EM-CCD) camera. The scintillator was designed with a water-permeable structure to allow contaminated water to flow through it, enabling direct detection of beta radiation in water. Radiation source measurements were performed in a dark room using a 90Sr–90Y beta source. Scintillation light generated in the CaF_2 scintillator was captured by the EM-CCD camera. The results demonstrated that the position of the beta source could be successfully visualized with acquisition times as short as 1 s, and the detected intensity increased with measurement time. Measurements conducted while moving the source confirmed that changes in source position could also be visualized, indicating the capability to monitor moving contamination in water. In addition, water infiltration tests confirmed that water could successfully pass through the scintillator structure. These results demonstrate that the proposed system is promising for real-time monitoring and visualization of beta-emitting radionuclides in radioactive liquid waste and aquatic environments.

Abstract

This paper presents a methodology for measuring the trajectories of high-energy electrons through materials utilizing a transmission electron microscope (TEM). This novel technique is implemented to diagnose and quantify the mechanism for enhanced radiation attenuation via nanostructures. Rather than an imaging technique, the TEM is applied to radiation shielding measurements as an adaptable electron source with functionality for various beam energies, amperage, alignments, and exposure times alongside an array of precise electron detectors. By utilizing energy filtering and direct electron detection capabilities, scattering profiles are measured with minimal background contributions. This TEM method is leveraged to describe particle transport in nanostructures. Palladium nanoparticles at various monodisperse sizes are synthesized via heat injection and deposited into an epoxy matrix. The palladium epoxy nanocomposites are sectioned with an ultramicrotome to thicknesses of 70 to 1000 nm containing nanoparticle sizes of 5 to 50 nm at 20% of the total weight fraction. Scattering profile measurements at various beam energies are conducted with a variety of sample thicknesses, nanoparticle sizes, and composite fractions. Scattering profile measurements also include bulk, homogeneous palladium samples in contrast to nanomaterials composed of identical atomic percentages. Simulation of the experimental scattering profiles demonstrate an understanding for the phenomena behind nanostructured attenuation enhancement, bolstering advanced nuclear technology via a foundational description for particle transport in nanostructures.

Abstract

New generation of vertex detectors must have excellent thermo-mechanical stability, and all-silicon ladders are considered as promising solutions for future detectors. However, power consumption asymmetries between the active area and periphery can induce large temperature gradients, and in some cases a combination of air and liquid cooling will be required to achieve homogeneous thermal profiles. Microchannel cooling offers a competitive alternative to traditional cooling systems. The short thermal path between the heat load and sink gives an increased thermal evacuation performance, combined with the reduced material needed for the integrated microchannels and the reduced Coefficient of Thermal Expansion mismatch between the cooling and sensor materials to obtain an optimized cooling for radiation detectors. The development of the technology needed for the integration of the sensor with the microchannels in a single piece is an ambitious challenge, as the conditions for the microchannel formation must be compatible with the sensor, requiring the optimization of the fabrication to ensure the compatibility with CMOS processes. As a demonstrator, all-silicon ladder prototypes with integrated cooling microchannels are presented. Power consumptions for the active area and periphery of the ladders are emulated using integrated aluminum heaters. The bulk in the active area is thinned from 600 to 50 microns, and the design of the microchannels cooling circuit, integrated in the periphery of the ladder, is optimized using finite-

element simulation packages. Variations of prototype ladders with different sizes, microchannel dimensions, and integrated using different wafer bonding techniques are fabricated and evaluated in detail in this work.

Abstract
We present performance calculations for a proof-of-concept, spin-selective neutron detector in which the magnetic field of a microfabricated planar superconducting coil controls the quantum mechanical absorption resonance in a multilayer structure. For first tests with cold neutrons, depolarization calculations favor a parallel over a meander geometry, the latter of which should nevertheless offer enhanced detector sensitivity in the ultracold neutron regime. Simulations predict that spin contrasts can be efficiently demonstrated using polarized cold neutron reflectometry at existing facilities.

Higher-Order Gain-Drift Correction in Magnetic Microcalorimeters for Decay Energy Spectrometry (#2186)

Ryan Wood[1,2], Igor Jovanovic[1], Geon-bo Kim[2]

[1] University of California, Berkeley, Nuclear Engineering, Berkeley, USA; [2] Lawrence Livermore National Laboratory, Livermore, USA

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. This material is based upon work supported by the Consortium for Nuclear Forensics under Department of Energy, National Nuclear Security Administration award number DE-NA0004142. This work was supported by the Laboratory Directed Research and Development program of Lawrence Livermore National Laboratory under Project No. 23-LW-043.

Abstract

Metallic magnetic calorimeters can provide excellent energy resolution for decay-energy spectrometry of alpha- and beta-emitting radionuclides, but temperature-dependent gain drift can broaden peaks during long acquisitions. This work compares two post-acquisition correction models for data acquired with a gold-erbium paramagnetic sensor in the MAGNETO-v neutrino experiment. The pre-trigger baseline is used as an event-by-event proxy for detector temperature. The lower-order model includes linear baseline dependence, whereas the higher-order model adds baseline-energy cross terms and second-order baseline dependence to capture nonlinear drift. Model parameters are estimated with a likelihood-based fit to known plutonium and americium reference peaks, and each event is calibrated by solving the fitted response model for deposited energy. Performance is evaluated from isotope-resolved peak widths in the corrected alpha-decay region of the spectrum. Across the reference groups considered here, the higher-order model produces consistently narrower fitted peaks, with the clearest improvements in the higher-statistical-weight isotope groups. These results indicate that higher-order baseline terms can improve spectral resolution when baseline-correlated drift is present.

Pixelated Array for Low-Energy Electron Beam Mapping (#2374)

Marcos Turqueti, Om Aggarwal

Lawrence Berkeley National Laboratory, Engineering Division, Berkeley, USA

Abstract

We present a low-energy electron beam position detector based on a segmented capacitive sensing architecture designed for precision monitoring of electron beams in the 500 eV to 2000 eV energy range. The detector employs a 3 mm × 3 mm capacitive sensor structure optimized for non-invasive beam position measurements with micrometer scale spatial resolution. Low-energy electron beams present unique diagnostic challenges due to their sensitivity to electromagnetic perturbations, beam spreading, and reduced signal levels. Conventional beam diagnostics often suffer from limited sensitivity or introduce disturbances that alter the beam trajectory.

The proposed detector addresses these limitations through a pixelated capacitive pickup array combined with low-noise front-end electronics and differential signal processing techniques. Variations in induced charge distribution along the sensing electrodes are used to reconstruct the transverse beam position with high precision while maintaining minimal interaction with the electron beam. The array enables accurate position tracking over extended beam paths and improves sensitivity to small beam displacements.

Analytical modeling and preliminary experimental characterization demonstrate that the sensor can resolve beam motion at the micrometer level across the targeted energy range. The detector response was evaluated as a function of beam energy, beam current, and electrode geometry, showing stable operation and high linearity under low-energy conditions. Noise mitigation strategies, including shielding and optimized capacitance matching, were implemented to preserve signal integrity and reduce environmental interference.

This detector architecture is well suited for applications requiring compact, high-resolution diagnostics of low-energy electron beams, including micro cathode ray magnetic probes, electron optics experiments, and vacuum electronic devices.

Abstract

Reliable long-term monitoring in nuclear decommissioning facilities is hampered by the absence of permanent power infrastructure and by the radiation fields that degrade conventional electronics. We present a scintillator-photovoltaic converter that captures ambient gamma radiation and transforms it into electrical energy sufficient for periodic wireless data transmission. The converter pairs a 750 cm³ CsI(Tl) crystal with a compact GaInP photovoltaic array mounted on a single end face, following a "large absorber, minimal semiconductor" strategy.) On-site evaluation inside a contaminated-material storage building at the Fukushima Daiichi Nuclear Power Plant (~35 mSv/h) produced 273 nW per module. Two parallel modules, combined with ultra-low-power energy management and a sub-GHz radio, achieved seven autonomous transmission bursts totaling 32 packets over a 30 m link during a three-hour observation window—without any external power supply or dedicated radioactive source.

Optimizing Tritium Uptake and Detection Sensitivity in a Metal-Hydride Gas Detector (#2734)

Praneeth Kandlakunta, Lei R. Cao, Tzu-Hsiang Lin, Rhys Young, Ashton Hoffman

The Ohio State University, Department of Mechanical and Aerospace Engineering, Columbus, USA

This research is supported by the U. S. Department of Energy / National Nuclear Security Administration under Award Number DE-NA0004196.

Abstract

The Metal-Hydride and Gas (MEGA) detector is a recently proposed approach for high-selectivity tritium (T_2) monitoring that combines hydrogen (H_2) storage metals with gas proportional counting. Previous work demonstrated the feasibility of T_2 absorption in palladium (Pd), formation of metal-tritide, and subsequent T_2 release into a proportional counter for measurement. In this work, we investigate pathways toward improving the overall detection efficiency of the MEGA detector through optimization of T_2 absorption, retention, desorption, and counting characteristics. A simplified efficiency framework is introduced to identify the dominant efficiency-limiting processes. The pressure–composition behavior of the Pd–H system is examined to evaluate approaches for enhancing isotope uptake at low T_2 partial pressures through reduced operating temperature and increased local pressure. Preliminary Monte Carlo simulations of tritium β-particle transport in Pd indicate strong self-absorption effects, with the simulated maximum penetration depth of 18.6-keV β-particles in Pd limited to a few hundred nanometers. These results support the need for optimized Pd geometry and efficient thermal desorption approaches to maximize gas-phase T_2 release and proportional counting efficiency. The present work establishes a quantitative framework for future optimization of MEGA detector sensitivity for environmental and nuclear safeguards applications.

Basic Development of a Wide-Field EUV Polarimeter for High-Energy Transient Sources (#3164)

Soken Kuwabara[1], Shuichi Gunji[2], Komei Chiba[1], Akira Takahashi[1], Mamoru Kitaura[2], Eiken Nakamura[3]

[1] Yamagata University, Graduate School of Science and Engineering, Yamagata, Japan; [2] Yamagata University, Faculty of Science, Yamagata, Japan; [3] Institute for Molecular Science, UVSOR Synchrotron Facility / Beamline Technical Staff, Aichi, Japan

The authors would like to thank the UVSOR staff for their technical support during the synchrotron radiation experiments. Portions of the manuscript preparation were assisted by a cloud-based AI language model.

Abstract

Polarization observations in extreme ultraviolet (EUV) band have not yet been achieved because it remains technically difficult to develop wide-field EUV detectors with sufficient sensitivity. However, EUV polarization measurements are expected to provide important insights into the emission mechanisms of gamma-ray bursts (GRBs) and ultraviolet flashes associated with supernova explosions. In this study, we propose a novel EUV polarimeter based on Lobster-Eye Optics (LEO), which combines a wide field of view with polarization sensitivity. Optical simulations show that EUV reflectivity on metal surfaces strongly depends on polarization. For example, at 40 eV and an incident angle of 75° on a gold-coated mirror, the reflectivity is about 40% for p-polarization and 60% for s-polarization, respectively. This difference produces an asymmetric cross-shaped image on the focal plane detector depending on the polarization direction. To verify this principle, we developed a test chamber and conducted a synchrotron radiation experiment using a gold-coated mirror and a microchannel plate (MCP) detector. By rotating the mirror around the beam axis, we measured the modulation of the MCP count rate and evaluated the detector modulation factor. The experimental results are presented and discussed in this paper.

Abstract

The KNU Advanced Positronium Annihilation Experiment (KAPAE) Phase II searches for invisible positronium decays using a compact 4π BGO scintillation calorimeter. Stable operation, efficient photon collection, and low-background performance are essential for this rare-event measurement. We report the cryogenic and underground performance of a chemically diffused BGO scintillator array developed for KAPAE Phase II.

The BGO crystal surfaces were chemically diffused to enhance photon collection and coupled to SiPM-based readout for low-temperature operation. At approximately −37 °C, reduced SiPM thermal noise and improved light collection yielded an energy resolution of 9% at 662 keV. The scintillation decay time was approximately 960 ns. This performance improves upon earlier BGO-based positronium calorimeters, including the ETH Zurich experiment, which reported an energy resolution of approximately 15% [1].

The detector was installed and operated at Yemilab underground. A continuous 120-day run demonstrated stable detector response, trigger operation, and long-term data-taking capability under cryogenic conditions. Calibration data were used to tune and validate a Geant4 detector simulation, which was applied to evaluate energy containment, gamma-ray leakage, and the expected sensitivity for invisible para-positronium decay searches. Based on measured performance and validated simulations, KAPAE Phase II achieves the expected sensitivity of 10−8 for invisible para-positronium branching-ratio measurements.

This study demonstrates that chemically diffused BGO scintillator arrays can provide stable, high-resolution calorimetric performance under cryogenic underground conditions.

Organic Scintillator Light Yield Models for Sub-MeV Neutrons in EJ301D and d-stilbene (#1369)

Christian A. Irvine[1,2], Tyler C. Borgwardt[1], Robert A. Weldon Jr.[1], John Mattingly[2]

[1] Los Alamos National Laboratory, NEN-2, Los Alamos, USA; [2] North Carolina State University, Nuclear Engineering, Raleigh, USA

This work was supported by the US Department of Energy through the Los Alamos National Laboratory. Los Alamos National Laboratory is operated by Triad National Security, LLC, for the National Nuclear Security Administration of U.S. Department of Energy (Contract No. 89233218CNA000001).

Abstract

Six commonly used models for neutron induced light yield in organic scintillators were fit and analyzed using measurements of a 2.54 cm diameter by 2.54 cm long right circular cylinder of EJ301D and a (5.08 cm)3 custom made cube of deuterated trans-stilbene-d12 (d-stilbene). Measured neutron energies spanned 300 keV to 2200 keV for the EJ301D scintillator and 200 keV to 2500 keV in d-stilbene. The model fits and experimental analysis methods were verified by examining the agreement between the predicted light output spectrum and the measured light output spectrum for several simulated quasi-monoenergetic neutron sources. Birks model inaccurately predicted highly quenched light yield for sub-MeV neutrons in both scintillators. The addition of a second order quenching term to the Birks model by Chou significantly improved the models accuracy, however its behavior is non-physical if extrapolated beyond the measured neutron energies. The model derived by Voltz accurately fit the measurement of both scintillators for all measured neutron energies. Further investigation into the ability to extrapolate based on these semi-empiric models would be valuable given the non-physical behavior of well-fitting models.

Dead time and self-absorption corrections at high uranium grade for total count rate gamma probes (#1014)

Bertrand Pérot[1], Thomas Marchais[1], Abdelwahab Miloudi[2], Hervé Toubon[2], Trevor Allen[4], Romain Mieszkalski[2], Youcef Bensedik[2], Sébastien Hocquet[2], Adrien Gruel[1], Clément Besnard-Vauterin[3]

Abstract

In high-grade uranium mines such as the Orano Canada Inc. (OCI) operated McClean Lake Mine, gamma logging probes deal with a non-linear behavior due to both gamma self-absorption in uranium and electronics dead-time, which may lead to a significant underestimation of the resources. Up to now, quantitative uranium grade measurements were conducted through coring and subsequent laboratory analysis. However, the SABRE mining method involves larger diameter drilling, making systematic coring impractical due to the additional costs. Therefore, Orano Mining and CEA have developed and qualified a combined correction for electronics dead-time and gamma self- absorption. These phenomena are significant above a uranium grade of about 1% w/w U, leading to huge resource underestimations at high grade, for instance nearly a factor 3 at 50% w/w U, just for self-absorption. In this work, we detail the tests conducted at Orano La Hague irradiator to estimate the dead-time of different NaI(Tl) and Geiger Muller probes, the MCNP Monte Carlo calculations to assess uranium self- absorption on a large uranium grade range, a new method developed to jointly correct for these two phenomena, and its experimental qualification through the comparison of gamma logging with core sample analyses from high-grade boreholes.

Abstract

The 1–30 MeV gamma ray observation holds key astrophysical signatures—nucleosynthesis, cosmic-ray interactions, and possible dark-matter signatures—yet remains the least explored window in high-energy astronomy. The electron-tracking Compton camera (ETCC) tracks the recoil electron to constrain the photon direction to a single point on the sky, enabling bijective imaging. We are developing the ETCC for SMILE-3, planned for 2028, extending the observation band to 5 MeV via a double-hit analysis. Beyond this, reconstructing pair-production events inside the time projection chamber (TPC) offers a further extension above ∼ 10 MeV and enables cross-calibration between Compton and pair-production channels in the same detector—an important advantage for MeV observations, where background control is critical. Additionally, identifying pair events removes a source of misreconstruction in the double-hit analysis, where atmospheric gamma rays above 10 MeV undergoing pair production are misidentified as Compton events and leak through the zenith-angle cut. We developed a geometry-based algorithm to identify pair-production events from the 3D point-cloud of TPC tracks. Voxelization and DBSCAN separate track clusters from noise; local PCA estimates direction vectors, and intersecting pairs define vertex candidates evaluated by a log-likelihood ratio (LLR) test. Accepted events are reconstructed from the vector sum of the two track directions. We validated the algorithm using inverse-Compton-scattered gamma rays at 3.3, 4.8, and 6.6 MeV from the UVSOR BL1U beamline. At 6.6 MeV, the 68% containment angle was 16.2◦ for beam-synchronous events and 12.0◦ for asynchronous events, consistent with the nuclear-recoil kinematic limit. Monte Carlo simulations with the SMILE-3 geometry are underway to quantify identification efficiency and leakage improvement.

Abstract

Dual gamma and neutron imaging is promising owing to their complementary characteristics, and has been widely applied in nuclear material monitoring, defect analysis of aerospace materials, and cultural heritage authentication. A gamma and neutron imager with an active area of about 20 cm × 20 cm is currently under development. The imager employs a home-developed Ce^{3+}-doped lithium glass scintillator coupled to 4096 silicon photomultipliers (SiPMs), each with a size of 3 mm × 3 mm. To achieve optimal imaging performance, each SiPM is individually read out using a newly custom-designed 64-channel application-specific integrated circuit (ASIC), designated CPRE64. A total of 64 CPRE64 chips are integrated into the system to read out the 4096 SiPM channels. This paper introduces the overall design of the two-dimensional (2D) neutron and gamma imager. A 2D neutron and gamma imager prototype, using a 25 mm × 25 mm × 5 mm scintillator coupled to an 8 × 8 SiPM array (3 mm × 3 mm pixel size), has been fabricated and characterized. The scintillator exhibits a light yield of approximately 4700 photon/MeV and an energy resolution of 14.5% for 662 keV gamma rays. Meanwhile, it provides a high light yield of roughly 7058 photon/neutron, which is approximately 1.18 times that of the reference GS20 glass. The baseline variation across CPRE64 channels was measured to be ± 10%, spanning from 1.3V to 1.7V, whereas the channel uniformity of the CPRE64 channels exceeded 90%. The prototype has been successfully used for gamma and neutron imaging, achieving an experimental neutron spatial resolution better than 1mm.

Abstract

Nuclear energy remains a pivotal low-carbon alternative for mitigating climate change, yet the management of radioactive waste presents significant technical and economic challenges. Optimizing waste characterization is essential to minimize disposal volumes and ensure safe decommissioning. This work evaluates a high-efficiency, portable Compton camera designed for the visualization and quantification of low- and intermediate-level waste (LILW).

The system was validated through three extensive field campaigns at the El Cabril disposal facility and the Santa María de Garoña nuclear power plant in Spain. These evaluations encompassed diverse waste containers and isotopic inventories to assess characterization performance in real industrial environments. Our findings demonstrate the robustness of Compton imaging, particularly regarding detection efficiency and reduced acquisition times. The system's performance was enhanced by integrating computer-vision techniques with GPU-accelerated Maximum-Likelihood Expectation Maximization (MLEM) algorithms, enabling real-time radiological-visual fusion.

Furthermore, we demonstrate the feasibility of 3D tomographic reconstructions derived from multi-pose measurements. A significant highlight is the first field deployment of GNVision, a novel dual-particle imager for simultaneous neutron and gamma-ray mapping, aimed at identifying actinide-bearing residues. These results

underscore the potential of advanced imaging to streamline waste classification and enhance safety in decommissioning workflows.

Development of a high-sensitivity portable gamma-ray imaging system for identifying radioactive material carriers (#1453)

Goeun Lee, Junyoung Lee, Taehyeon Eom, Jaeho Cho, Sehyun Jang, Chan Hyeong Kim

Hanyang University, Nuclear engineering, Seoul, South Korea

Abstract

Gamma-ray imaging is an emerging technology to identify individuals smuggling radioactive materials at international points of entry. However, imaging moving subjects requires high efficiency due to the limited data acquisition time as sources pass the imaging system. We developed a high-sensitivity gamma camera named the portable fast gamma imager (pFGI). The pFGI integrates an imaging module, an RGB-D camera, and other components into an enclosure. The imaging module combines Compton and coded aperture modalities using two position-sensitive detectors and a MURA coded aperture mask. Each detector comprises a monolithic NaI(Tl) scintillator (14.6×14.6×2.5 cm^3) coupled to a 3×3 square-type photomultiplier tube array. The detectors are placed 16 cm apart, with the mask 6 cm in front of the front detector. To achieve superior imaging performance across a broad energy range, a hybrid imaging method was employed, which acquires coded aperture and Compton images, respectively, and then fuses them via pixel-wisemultiplication. Furthermore, an AI-based motion-compensated method was used to integrate data along the moving subject's trajectory. The YOLOv11 and BoT-SORT algorithms were applied to the RGB images acquired from the RGB-D camera to extract displacement vectors for each subject; then, the radiation image for each subject was translated and fused according to the trajectories. The pFGI achieved a 7° angular resolution and high sensitivity, imaging the location of a 137Cs source, producing an incremental dose rate of 0.1 μSv/h within 1 s. Additionally, in a dynamic multi-person scenario, the imager successfully and continuously imaged the moving source and identified the source carrier among multiple people. These results highlight the pFGI as a robust solution for national security.

Abstract

Radioactive materials released during the accident at the Fukushima Daiichi Nuclear Power Station were deposited not only on land surfaces but also in aquatic environments such as irrigation ponds. Monitoring radiation levels in these environments is important for environmental assessment and decontamination activities. In this study, a waterproof gamma-ray spectrometer based on a Ce-doped $Gd_2Si_2O_7$ (Ce:GPS) scintillator coupled with a photomultiplier tube was developed for underwater radiation measurements. The detector employed a 10 mm × 10 mm Ce:GPS scintillator and an FPGA-based data acquisition system for event-by-event signal processing and energy spectrum acquisition. To enable pond-bottom measurements, the detector was integrated into a pipe structure approximately 4 m in length. Field measurements were conducted in an irrigation pond in Fukushima Prefecture, where the detector was submerged and placed on the pond bottom. A clear 662 keV photopeak originating from cesium-137 was observed, and the measured energy resolution was 9.8% FWHM. Energy spectra were also measured at different heights above the pond bottom. The cesium-137 photopeak was clearly detected at the bottom and at 50 cm above the bottom, whereas scattered gamma-ray components became dominant at greater heights because of attenuation and scattering in water. The results demonstrate that the developed waterproof Ce:GPS spectrometer is effective for in-situ underwater gamma-ray measurements and radionuclide identification in aquatic environments contaminated by radioactive cesium.

Dual Time-Over-Threshold Energy and PSD Readout of SiPMs Using FPGA-Based TDCs (#1724)

Aaron Nowack[1], John Leland[2,1], Erik Brubaker[1], John Steele[1], Melinda Sweany[1]

[1] Sandia National Laboratories, Dept 08647 - Radiation and Nuclear Detection Systems, Livermore, USA; [2] University of Illinois, Urbana-Champaign, Department of Nuclear, Plasma, and Radiological Engineering, Urbana, USA

Abstract

Independent readout of highly pixelated organic scintillator detectors is needed for next-generation associated particle imaging, neutron radiography, and single-volume scatter cameras. Field-programmable gate arrays (FPGAs) are an attractive solution as they have hundreds to thousands of IO pins and can be programmed for a variety of applications while minimizing cost as compared to ASICs. We detail a dual time-over-threshold (ToT) method for measuring the deposited energy and pulse width of gamma and neutron interactions in scintillator using a Time-to-Digital Converter (TDC) realized with an FPGA and minimal external components. We compare a simple DC threshold and an active feedback rising edge signal for PSD and energy estimation. Simulated ToT results using digitized data are presented, with hardware details for an upcoming data campaign. For each circuit, the performance of energy resolution and PSD capability is weighed against the complexity and power requirements of the external analog components. In this work we present each of these approaches for SiPM readout, detail current progress, and experimental results.

Abstract

This work, conducted within the framework of the AIDER project, presents the design and preliminary characterization of an electronics readout architecture for SiPM-based Compton cameras (CCs) in nuclear applications. The system includes two front-end units, serving the absorber and the scatterer layers. Each module integrates four GAMMA ASICs to interface with up to 64 SiPMs per layer, performing individual charge integration

while providing an aggregated sum-current output. To mitigate amplitude-walk effects over the broad energy spectra typical of Compton imaging, time stamps are extracted by a custom designed Constant Fraction Discriminator (CFD) circuit. A central FPGA with embedded Time-to-Digital Converters (TDCs) synchronizes energy and timing data across both layers. A pre-trained Artificial Neural Network (ANN) is embedded directly into the FPGA logic to provide real-time estimation of the interaction position, reducing data throughput. SiPM are biased by a custom module that dynamically compensates for temperature fluctuations. The electronics, coupled with a 25 mm x 25 mm x 5 mm LaBr3 scintillator and a 16 SiPMs tile, yielded an energy resolution of 3.6% FWHM at 662 keV. Preliminary characterization of the CFD circuit with current pulses injected into the ASICs yielded a 140 ps resolution at 511 keV maintaining a sub nanosecond resolution down to 45 keV. The amplitude walk on such dynamic range was limited to 2.15 ns.

Abstract
In this work, we present a scalable high-performance readout system for LYSO-coupled SiPMs. The project aims to enable real-time beam range monitoring in proton therapy through Prompt Gamma Imaging (PGI), detecting prompt gamma rays emitted during proton–tissue interactions [1]. This application requires operation over a wide energy range, from 3 MeV to 10 MeV, together with high count-rate capability up to 1 Mcps/channel.
The resulting platform is suitable for a broad range of gamma-ray detection applications. A compact DAQ board has been developed integrating all the electronics required for gamma event acquisition, processing, and data transmission without the need for external units [2]. The system is able to detect gamma rays with energies above 10 MeV using 12-bit energy digitization and 300 ps (FWHM) timing resolution.

The module is connected to LYSO-coupled SiPMs (Hamamatsu S14160-6015PS) featuring a 6 × 6 mm² photosensitive area and 15 µm pixel pitch. Tests with calibration sources show a 10.2% FWHM resolution at 511 keV and 6.2% at 1275 keV.
A custom ASIC specifically developed for high-energy gamma-ray detection is used for the readout of SiPM currents. With a minimum integration and readout time of 350 ns, the ASIC supports output count rates above 1 Mcps/channel.
While each module supports 32 SiPM channels, multiple identical modules can be connected in a daisy-chain configuration to support larger detector arrays. The PCB mechanical design allows multiple boards to be stacked without inactive regions between modules, with the only limitation being the available 10 Gbps transmission bandwidth.

High-Rate FPGA-Based Fully Digital SiPM Readout for Photon-Number-Resolving Measurements in Quantum Optics and Quantum Communications (#2050)

Stefano Carsi[1,2], Andrea Abba[1], Alessia Allevi[2], Alex Pozzoli[2], Marco Lamperti[2]

[1] Nuclear Instruments SRL, Lambrugo, Italy; [2] Università degli Studi dell'Insubria, Dipartimento di Scienza e Alta Tecnologia, Como, Italy

Abstract
Photon-number-resolving (PNR) detection based on Silicon Photomultipliers (SiPMs) is emerging as a promising approach for high-rate quantum optics and quantum communication experiments, particularly for the possible implementation of hybrid schemes. We present a fully digital SiPM readout platform combining a 14-bit, 1 GS/s waveform digitizer with a real-time FPGA-based signal-processing chain optimized for fast charge extraction and photon-number reconstruction. The system is implemented on an open-FPGA architecture programmable through the Sci-Compiler framework, enabling custom firmware development without dedicated HDL design.
The firmware performs real-time baseline restoration, digital pole-zero compensation, synchronous triggering, and charge integration entirely inside the FPGA pipeline at full sampling rate. The system supports synchronous operation with externally or internally triggered laser sources and enables deterministic acquisition windows with nanosecond-scale integration gates.
Different Hamamatsu SiPM models were characterized using coherent and twin-beam optical states to evaluate the impact of detector gain, pixel pitch, pile-up, and photon detection efficiency on photon-number reconstruction. Measurements demonstrate reliable operation from mean photon numbers well below 1 up to more than 50

detected photons per pulse at repetition rates up to 1 MHz, with operation extendable toward 10–20 MHz depending on the analog front-end configuration. The digital processing chain significantly improves peak separation, dynamic range, and noise performance compared with conventional boxcar-based acquisition systems. The presented architecture demonstrates how modern FPGA-based real-time digital processing can transform SiPM detectors into scalable, high-speed PNR systems suitable for next-generation quantum optics instrumentation and quantum communication protocols.

Abstract

Direct positron emission imaging (dPEI) enables imaging of positron-emitting radionuclide distributions without tomographic reconstruction by directly localizing annihilation events using ultrafast time-of-flight measurements. This modality was first demonstrated experimentally in 2021 using two Cherenkov-radiator-integrated microchannel plate photomultiplier tubes (CR-IMPs) read out by an oscilloscope. However, to scale to a larger number of channels for clinical applications, the oscilloscope must be replaced with an embedded front-end and digitizer. In this study, a dPEI acquisition chain for multi-channel readout was designed using two CR-IMPs, a FastIC+ front-end, and a tapped delay line time-to-digital converter implemented inside an UltraScale+ FPGA. A single-shot RMS precision of 4.0 ps was achieved by the front-end and the TDC when measuring pulses from a function generator. This timing precision is sufficient to digitize CR-IMP signals while preserving the timing performance required to approach the best coincidence timing resolution (CTR) currently measured using an oscilloscope. After evaluating the combined FastIC+ and TDC system, a complete readout chain from two CR-IMPs through the FastIC+ to the TDC was successfully configured, and coincidence events from a Na-22 source were successfully acquired during preliminary operation. We are currently optimizing the front-end parameters to achieve the best CTR between the two CR-IMPs. This study highlights the capability of the FastIC+ to read out CR-IMP signals and the ability of the combined FastIC+ and FPGA-based TDC system to digitize events with sufficient precision for dPEI.

TEMPOROC3 : A 64-channel SiPM read-out chip for time-of-flight measurement on monolithic crystal (#3068)

Salleh Ahmad, Jean-Baptiste Cizel, Cyrille Derrien, Julien Fleury, Amar Haddar, Maxime Morenas, Florent Perrez, **Vsevolod Yeroshenko**

Weeroc, Villebon-sur-Yvette, France

Abstract

TEMPOROC3 is a 64-channel mixed-signal SiPM read-out application-specific integrated circuit (ASIC) designed in TSMC130 technology. The ASIC aims at measuring the energy with a 10-bit analogue-to-digital converter (ADC), time-of-arrival (TOA) and time-over-threshold (TOT) with a 40-ps bin time-to-digital converter (TDC). The analogue front-end offers a dynamic range up to 500 pC. The dual discriminator allows for measuring either two TOA at different threshold levels or the time between a rising and falling edge, giving a TOT. The dual-gain charge measurement integrates the input signal over a tuneable range from 20 to 300 ns. The 64 channels are divided into 4 clusters, each outputting data at 320 Mbps. The clusters can be synchronised to stream all channel data whenever a channel from the matrix has triggered. The number of triggered channels (per cluster) required to launch the data serialisation is programmable, as well as the window duration for accepting new triggers. At 450 kEvents/s per cluster (with 1 TDC + 1 ADC per channel), the power consumption is about 8 mW per channel. The trigger scheme for the monolithic matrix readout was successfully validated by acquiring a gamma spectrum of an ^{11}Na source with a large LYSO(Ce) crystal coupled to a 61-channel SiPM. Event filtering using a charge discriminator was validated, allowing for data rate reduction in the ASIC. Temporal characteristics were evaluated using external trigger, charge injection, laser pulses with SiPM, and coincident gamma from an ^{11}Na source. Measurements in coincidence between 2 channels from 2 ASICs have shown TDC coincidence time resolution (CTR) as low as 60 ps FWHM. Coincident annihilation gamma measurement using LYSO(Ce) crystals with SiPM demonstrated spatial sensitivity to the source displacement, providing CTR as low as 139 ps FWHM. TEMPOROC3 has been shown to be a versatile read-out ASIC with numerous configuration parameters that can be applied in ToF-PET, Compton cameras, LIDAR.

Very-High-Energy Electron FLASH Radiotherapy at the PEER Beamline - Dosimetry and Biological Benchmarking (#2494)

James Cayley[1], Dean Cutajar[1], Elette Engels[2,1], Chelsey Skee[1], Anatoly Rosenfeld[1], Yaw-Ren E. Tan[3], Michael Lerch[1]

[1] University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia; [2] Peter MacCallum Cancer Centre and University of Melbourne Sir Peter MacCallum Department of Oncology, Melbourne, Australia; [3] ANSTO, Australian Synchrotron, Melbourne, Australia

Abstract

Very-high-energy electrons delivered at ultra-high dose rates, are being investigated for their promise within radiotherapy to treat deep-seated tumours. VHEE FLASH radiotherapy research requires two major components; a real-time dosimeter that remains linear at the required dose-per-pulse, and an accelerator that is stable, biologically benchmarked, and suitable for in vivo studies. Investigations have been conducted at the Pulsed Energetic Electrons for Research (PEER) beamline of the ANSTO Australian Synchrotron to realise this reality. Utilising a 100 MeV electron linac, PEER provides irradiation fields comprised of 100 ps bunches with a 2 ns spacing, forming bunchtrains with average and instantaneous dose-rates as high as 10^8 Gy/s and 10^9 Gy/s, respectively. The MOSkin detector was tested for linearity with a dose-per-pulse as high as 23 Gy within 200 ns. During this work, EBT-XD radiochromic film was employed as a reference dosimeter, however, a dose-rate dependence of the film was discovered. This was confirmed with another experiment which allowed calculation of a correction factor, enabling use of the film as an independent measurement of dose. Three cell lines (A549, T98G, and MDCK) were irradiated utilising real-time dosimetry, and mouse cadavers were irradiated to assess the feasibility of small animal experiments. These results support PEER as being suitable for future in vivo VHEE FLASH research.

Abstract

This work investigates the feasibility of using the ALPIDE pixelated detector for two-dimensional microdosimetry applications in proton therapy. The detector offers several advantages for microdosimetry, including low noise, fast readout capability, flexible spatial sampling, and very high spatial resolution. Detailed Geant4 simulations were developed to model an experimental setup using an 80 MeV proton beam passing through different aluminium thicknesses. A strong agreement was observed between the responses of the ALPIDE detector and the SOI microdosimeter, demonstrating the capability of ALPIDE to accurately characterise LET distributions in proton radiation fields. In addition, the proposed calibration approach showed that the cluster size measured by the ALPIDE detector can be reliably converted to LET in silicon. Thanks to its pixelated architecture, arbitrary groups of pixels can be selected and analysed, enabling high-resolution two-dimensional LET mapping of complex radiation fields. These results demonstrate the strong potential of the ALPIDE detector as a versatile and cost-effective tool for advanced microdosimetry and proton beam LET_d characterisation.

AlphaBeast : A CMOS-based detector for real-time neutron production monitoring (#1169)

Lucia Victoria Garcia Garcia[1], Nicolas Arbor[1], Djokhar Betelgueriev[1], Stéphane Higueret[1], The-Duc Le[1], Jean-Michel Horodynski[2]

[1] Université de Strasbourg, CNRS, IPHC UMR 7178, Strasbourg, France; [2] Ingénierie Radioprotection Sûreté Démantèlement (iRSD) - CNRS, Paris, France

Abstract

Neutrons produced around particle accelerators are a major concern for radiation protection in research, medical, and industrial facilities due to their contribution to occupational exposure, patient dose, and material activation. Accurate characterisation of neutron fields is therefore essential, but conventional techniques such as activation foils, Bonner sphere systems, and solid-state nuclear track detectors are limited by their lack of real-time capability. In this work, we present the AlphaBeast, a CMOS-based detector designed for real-time monitoring of thermal and fast neutrons. This sensor has been designed as an electronic alternative to solid-state track detectors, using polyethene and 10B converters for fast and thermal neutron detection with on-chip discrimination thresholds. The system was calibrated using the irradiation facilities available at the Institut Pluridisciplinaire Hubert Curien in Strasbourg, France. A GATE/Geant4 Monte Carlo model was developed to simulate the detector response and optimise its performance. The AlphaBeast sensor was then tested in various mixed radiation fields, including radiotherapy rooms and accelerator casemates. Experimental results show good agreement with simulations and demonstrate its potential for real-time neutron monitoring in particle accelerator facilities.

Abstract

Fully depleted silicon pnCCD sensors are used for X-ray spectroscopy in applications ranging from X-ray astronomy to synchrotron radiation sources and free-electron lasers, due to their outstanding capabilities, such as high energy resolution, low electronic noise and excellent quantum efficiency. At HLL, a new series of pnCCD sensors with a 36 µm pixel size has been fabricated to investigate the performance of small-pixel pnCCD devices. Applications requiring high spatial resolution can benefit from smaller pixel sizes, utilizing position reconstruction based on charge sharing. This contribution focuses on the systematic comparison of different designs within this pnCCD production run. The investigated sensors include devices based on our standard JFET amplifier, as well as variants with modified readout anodes, different options for the biasing of the MOS structures between the p-registers, and an option for a sensor design with self-aligned channel guide implants. Since the devices share the same basic geometry and sensor thickness, their comparison allows design-dependent effects on the detector performance to be directly assessed, while also exploring possible simplifications of the fabrication process and the overall detector system. For this purpose, the sensor variants are tested under comparable operating conditions using a newly developed experimental setup at HLL. The sensors are read out in a column-parallel architecture using the VERITAS 2.1 ASIC. Their spectral performance is evaluated in terms of noise behavior, gain uniformity, charge transfer inefficiency, and energy resolution. The observed performance differences between the variants will be discussed as a basis for identifying optimization paths for future pnCCD sensor designs.

fine-pitch HPGe strip detectors for high-rate gamma-ray spectroscopy and imaging (#3145)

Joanna M. Szornel[1]

[1] Lawrence Berkeley National Laboratory, Nuclear Science Division, Berkeley, USA; [2] Lawrence Berkeley National Laboratory, Nuclear Science Division, Berkeley, USA; [3] Lawrence Berkeley National Laboratory, Berkeley, USA; [4] Lawrence Berkeley National Laboratory, Berkeley, USA

This work was supported by the Laboratory Directed Research and Development (LDRD) program of Lawrence Berkeley National Laboratory under Contract No. DE-AC02-05CH11231 with the U.S. Department of Energy.

Abstract

A prototype high-purity germanium (HPGe) double-sided strip detector has been developed to maintain high energy resolution and high throughput at count rates relevant to MHz-rate gamma-ray spectroscopy and imaging. Conventional HPGe detectors provide excellent energy resolution but suffer from throughput loss and resolution degradation at elevated count rates, limiting their use in applications such as beam diagnostics, nuclear decommissioning, medical imaging, and prompt spectroscopy of superheavy elements.

This work presents the design, fabrication, and characterization of fine-pitch HPGe double-sided strip detectors developed for high-rate spectroscopy and imaging. A 0.5 mm strip pitch detector geometry was selected using analytical calculations and numerical simulations of efficiency, charge collection, throughput, timing, energy resolution, and position resolution. This prototype demonstrated an energy resolution of 1.8 keV FWHM at 662 keV under low-rate conditions, consistent with predicted performance, and has now undergone additional characterization at higher rates. Extensive characterization has also been performed on 1.16 mm-pitch HPGe strip detectors, providing a broader experimental basis for evaluating fabrication yield, leakage current, strip-to-strip uniformity, charge sharing, charge loss, and spectroscopic performance.

Results from both the 1.16 mm-pitch and 0.5 mm-pitch detectors will be presented. Energy resolution and throughput are evaluated as functions of shaping time, strip geometry, and incident count rate. These results demonstrate progress toward fine-pitch HPGe detector systems capable of high-resolution spectroscopy, three-dimensional position sensitivity, and sustained performance in high-rate environments.

This work was supported by the NASA Astrophysics Research and Analysis (APRA) program, grant 80NSSC22K1881. The Compton Spectrometer and Imager is a NASA Explorer project led by the University of California, Berkeley with funding from NASA, United States under contract 80GSFC21C0059.

Abstract

We performed a high-energy proton irradiation on a cross-strip germanium detector with the goals of measuring the subsequent loss to detector spectral resolution and characterizing the effectiveness of high-temperature annealing in repairing radiation damage. This work aims to address the expected radiation damage to the Compton Spectrometer and Imager (COSI) during two-year primary mission in low-Earth orbit and evaluate methods for maintenance of spectral resolution. COSI's cross-strip germanium detectors are susceptible to damage induced by the space radiation environment. Negatively charged dislocations induced by high-energy protons trap charge carriers as they drift in the applied bias voltage. The result is a degraded hole-collection signal characterized by widened spectral lines and loss to detector spectral resolution. We irradiated a non-flight detector with a fluence of $1.1 \cdot 10^7$ p^+/cm^2 — COSI's expected exposure over prime mission (95% confidence level). After irradiation, we executed a series of high-temperature anneals aimed at physically repairing the damaged germanium. We track spectral resolution by measuring the full width half maximum (FWHM) of the 662 keV spectral line emitted by the isotope Cesium-137. We repaired widened FWHMs through high-temperature annealing to within 12% of its preradiation value, repairing to 2.97 keV compared to the original 2.67 keV. We track spectral resolution across annealing processes and characterize a timescale for repair. We find the anneal time needed to repair damage from COSI's primary mission within 1% of the spectral broadening from residual damage. We project the repair time required at 90°C to be 54 +/- 10 hours.

Abstract

Neutron imaging arrays are critical tools in nuclear non-proliferation, with applications in neutron source localization in wide-area source searches and cargo inspections. However, they commonly have large form factors due to needing large data acquisition systems, complicating deployment. A solution with simplified data acquisition is needed to make portable and field-deployable neutron imaging arrays. Organic scintillator-based neutron imaging arrays typically require pulse shape discrimination (PSD) to differentiate between neutron and gamma-ray events. This method requires full waveform data acquisition, which results in a high data throughput, and utilizes expensive analog-to-digital converters. In order to alleviate the need for full waveform acquisition, this work seeks to develop a system that instead leverages time-of-flight particle discrimination. To discriminate neutrons from gamma events using time-of-flight particle discrimination, a Segmented Organic Neutron Imager Cell, SONIC, has been constructed of 64 5x0.6x0.6 cm3 bars of EJ200. 14 of the 16 tested bars show typical pulse-integral spectra for Cs-137. This work details the introductory characterization of this imager array and evaluates its validity for future work in achieving a field-deployable, handheld neutron scatter imager.

NSS-05-02

Development of an omnidirectional neutron imager with fractal geometry (#1531)

Nishiki Matsubayashi[1], Tatsuo Torii[2], Miyuki Sasaki[3], Shunsuke Kurosawa[4]

[1] Tokyo University of Agriculture and Technology, Tokyo, Japan; [2] Fukushima University, Fukushima, Japan; [3] Japan Atomic Energy Agency, Minamisoma, Japan; [4] Nagoya University, Nagoya, Japan

In making the detector, we got help from N. Miyazaki and Y. Furuta at Clear Pulse Co., Ltd., and T. Sugita at SSL Inc. for response analysis. In addition, this research was conducted using funds from the JAEA/CLADS project (problem-solving program for decommissioning research, FY2024).

Abstract

In areas where radiation sources are diffused three-dimensionally, it is important to develop a compact imaging sensor that can detect radiation distributions in the 4π direction. A radiation imager that detects the distribution of radiation sources with a fractal Sierpinski tetrahedron shape was developed before. The imager has 16 sensors arranged in a Sierpinski tetrahedron shape, with the space between the sensors filled with a shielding material. We have been developing a neutron imager to measure radiation distribution within the site of the Fukushima Daiichi Nuclear Power Plant (FDNPP) and in the environment contaminated by the FDNPP accident. The reactor buildings contain large amounts of radiation sources. Since the nuclear fuel and debris contained in the reactor pressure vessel (RPV) will be removed in the future, it is extremely important to identify neutron sources originating from nuclear fuel in high dose rate areas for criticality management and radiation protection of workers. Therefore, we developed a compact omnidirectional neutron imager to locate neutron sources in the reactor building. This sensor consists of thin triangular scintillators (^{6}LiF/ZnS:Ag) for neutron detection attached to a tetrahedral acrylic surface and arranged in a Sierpinski tetrahedron shape, with B_4C mixed with resin for neutron shielding filled between the sensors. In this presentation, we report the results of performance evaluations of the imager using a neutron source and research reactor.

Neutron Spectroscopy Using a Spatially Resolved He-3 Slab Detector

(#2047)

Madeline L. Lockhart[1], Jason P. Hayward[1], Amanda Youmans[2], Phil Kerr[2]

[1] University of Tennessee, Department of Nuclear Engineering, Knoxville, USA; [2] Lawrence Livermore National Laboraatory, Livermore, USA

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
This material is based upon work supported by the Department of Energy National Nuclear Security Administration through Defense Nuclear Nonproliferation's Enabling Capabilities in Technology Consortium under Award Number DE-NA0004197.

Abstract

This work presents a He-3 based slab detector for neutron spectroscopy that leverages spatially resolved detector response to infer incident neutron energy. In moderated detector systems, neutron energy information is typically degraded prior to detection, complicating spectrum unfolding. The proposed detector addresses this limitation through channel-by-channel list-mode acquisition, enabling analysis of spatial response variations correlated with neutron energy. Additional moderating and absorbing configurations are investigated to improve spectral sensitivity. A model of the detector is developed using Monte Carlo simulation and benchmarked against experimental measurements with monoenergetic neutron sources. This model will be used to generate energy-dependent response functions for use in spectral unfolding. Results indicate that combining spatial response information with multiple detector configurations will improve the conditioning of the neutron spectrum unfolding problem and enhance reconstruction accuracy. This approach provides a pathway toward information-optimized neutron spectrometry for nuclear security and safeguards applications.

Residual Interpulse 14-MeV Neutron Emission in Active Interrogation with Neutron Generators (#2076)

Valentin Fondement[1], Igor Jovanovic[2]

[1] University Of Michigan, Nuclear Engineering & Radiological Sciences, Ann Arbor, USA; [2] University of California, Berkeley, Nuclear Engineering, Berkeley, USA

This work has been supported in part by the US Department of Homeland Security, Countering Weapons of Mass Destruction (CWMD) Office, Academic Research Initiative
cooperative agreement number 21CWDARI00040-01-0.

Abstract
We report residual 14 MeV neutron emission between pulses of a Thermo Fisher Scientific P 211 DT neutron generator operated at 100 Hz with a 0.1% duty cycle. Using a liquid organic scintillator with pulse-shape discrimination, we detect a significant population of neutron events with light output consistent with DT neutrons. The interpulse time structure follows a two-component exponential decay with time constants of 0.8 ms and 4.7 ms, inconsistent with ^{17}N β-delayed neutron emission. The interpulse yield represents 0.1% of the total emission (~10^{-6} of instantaneous pulse intensity). These results demonstrate that the assumption of zero interpulse emission can be violated even when both the ion source and the high voltage are nominally pulsed, with direct implications for low-SNR delayed-signature measurements.

We would like to thank Dr Jochen Stahn (PSI) and Dr Davide Raspino for providing beam time and their support during the measurements at the AMOR and MORPHEUS instruments at the Paul Scherrer Institute (CH) and the EMMA beamline in the ISIS facility at the Rutherford Appleton Laboratory (UK).

Abstract
The European Spallation Source (ESS) requires advanced neutron-beam monitors capable of stable operation under high-rate conditions while maintaining low beam attenuation. To address these requirements, a Micromegas-based Neutron Flux Monitor (NFM) has been developed by the ESS Detector Group in collaboration with DEDIP

(IRFU) and CEA Saclay. The detector employs a novel bulk Micromegas implementation directly on AlMg3 alloy substrates, minimizing the use of hydrogen-rich materials and therefore reducing neutron attenuation and moderation effects along the beamline. Initial detector characterization using X-ray sources demonstrated good gain uniformity, stable high-gain operation, and good energy resolution. Subsequent neutron measurements performed with different gas mixtures and front-end electronics confirmed stable operation under representative ESS-like conditions. Measurements performed at the EMMA beamline at ISIS investigated detector performance at high neutron rates and provided important input for the optimisation of the final NFM readout architecture for future ESS deployment.

Abstract
Fast neutron spectroscopy has the potential to offer critical information for safeguards, nonproliferation, and field radiation detection applications where neutron energy distributions provide source characteristics inaccessible through conventional moderated neutron counters. Traditional portable neutron detection systems primarily rely on moderation and thermal neutron counting, which remove incident neutron energy information and limit spectroscopic capability. In this work, the nSpec system is developed as a handheld fast neutron spectrometer utilizing four novel deuterated polystyrene (dPS) scintillator detectors coupled to photomultiplier tubes in a compact, field-deployable architecture. By leveraging neutron--deuteron elastic scattering interactions, the system preserves energy-dependent neutron response while maintaining portability suitable for operational environments. Pulse shape discrimination is employed to separate neutron and gamma interactions, while detector response

matrices (DRMs) derived from high-flux neutron characterization are used to reconstruct incident neutron spectra through maximum likelihood expectation maximization (MLEM) unfolding. Prototype evaluations using representative neutron sources, including AmBe and Cf-252, demonstrate successful spectral unfolding and source discrimination capability. Ongoing development focuses on onboard electronics integration, firmware implementation, shielding optimization, and validation against simulated and experimental DRMs. These results establish nSpec as a promising pathway toward practical handheld fast neutron spectroscopy for safeguards and field applications.

Abstract

Neutron production cross-sections are critical for dose assessment in particle therapy and space radiation protection, yet double-differential data remain scarce. We present a consistent framework for Time-Of-Flight (TOF)-based measurement built around the use of Low Gain Avalanche Detectors (LGADs) segmented into strips on the primary beam, enabling large statistical samples and precise time measurement, and a secondary neutron detector split into layers to accurately reconstruct neutron production as a function of kinetic energy and angular direction. A preliminary beam test was conducted to validate the methodology. The setup comprises an 8-strip beam monitor for primary particle tagging, a $LaBr_3$(Ce) scintillator with Silicon Photomultiplier (SiPM) readout as secondary radiation detector, and a plastic veto for charged-particle rejection. Neutron kinetic energy is reconstructed via relativistic TOF analysis from approximately 16 MeV to several hundred MeV. A novel Beer-Lambert fitting approach enables efficiency-independent neutron flux estimation from the attenuation pattern along the detection depth, overcoming systematic uncertainties of conventional scaling methods. Monte Carlo (MC) simulations validate both TOF distributions and flux reconstruction at the few-percent level, with computed cross-sections in good agreement with MC truth values. Combined with a rotary-translation stage enabling systematic angular scanning for full double-differential cross-section mapping, the proposed approach provides a robust and scalable framework for neutron production measurements in fragmentation events, with direct application to out-of-field dose characterization in particle therapy and astronaut radiation exposure assessment.

Abstract

Novel Photon-to-Digital Converters (3D-PDCs) are arrays of Single Photon Avalanche Diodes (SPADs) vertically-integrated with low power CMOS digital readouts, offering high timing precision (<200 ps FWHM) and individual-pixel control. As single-photon counters, 3D-PDCs can be coupled to scintillators for radiation detection. This talk will discuss the first 3D-PDC measurements of fast neutrons. The 3D-PDCs are used to read out an organic plastic scintillator with Pulse Shape Discrimination (PSD) capabilities, making incident neutrons and gamma rays discernible by the pulse shape of the induced scintillator signal. First PSD results will be shown and compared to standard commercial silicon photomultipliers.

ARES: A Web-Based Platform for Registration, Access, and Analysis of Radiation Simulation Results (#3019)

Sacha E.R. Medaer[1], Carlos H. Ferreira Brito Filho[2], Pedro Glaser De Senna[2], Andre Freitas Pacifico[2], Joel Closier[1], Gloria Corti[1]

[1] CERN, LHCb Collaboration, Geneva, Switzerland; [2] Universidade Federal do Rio de Janeiro, COPPE/EE/IF, Rio De Janeiro, Brazil

Abstract

Radiation simulations are essential for the design, operation, upgrade, and radiation protection assessment of high-energy physics experiments and other complex accelerator or irradiation facilities. However, their outputs are often difficult to organise, document, retrieve, compare, and share consistently, particularly when many studies, configurations, and users are involved. We present the Analysis platform for Radiation Environment Simulations (ARES), a web-based system developed within the LHCb experiment to support the workflow from registration to analysis of radiation simulation results obtained with the FLUKA particle transport code. ARES provides a database-backed interface for registering radiation estimators together with metadata describing the simulation context, scoring configuration, estimator location, and other relevant information. This structured registration makes results traceable, searchable, reproducible, and easier to reuse. Users can browse and query available estimators through a dedicated search interface and open selected data in a standalone visualisation and analysis service. The platform has been deployed for LHCb radiation studies covering prompt radiation and induced activity use cases, supporting quantities such as fluence, dose, and activation-related estimators. By centralising validated results and providing common tools for access and analysis, ARES improves collaboration between stakeholders involved in simulation production, detector studies, operations, upgrades, and radiation protection. This work demonstrates that a dedicated data-management and analysis layer can make radiation simulations more accessible and more effectively exploitable within a large experimental environment. Future developments include support for additional Monte-Carlo based codes and broader applicability beyond current LHCb use cases.

Monte Carlo simulation of a new Optical Neutron Detector geometry for generation-IV Sodium-cooled Fast Reactors (#1285)

Valentin Gerenton, **Valentin Gerenton**, Philippe Filliatre, Philippe Filliatre, Grégoire De Izarra, Grégoire De Izarra

CEA, DEN / DER / Instrumentation, Sensors and Dosimetry Laboratory, Saint-Paul-lez-Durance, France

This work was supported by the CEA, DEN, Reactor Research Department, Saint-Paul-lez-Durance, France.

Abstract

Generation-IV sodium-cooled fast reactors impose severe constraints on neutron flux measurement instruments, particularly due to sustained temperatures that can exceed 550 °C [1]. In this context, optical neutron detectors (ONDs) represent a promising alternative to conventional fission chambers. These devices convert the kinetic energy of fission fragments into optical photons via gas-plasma luminescence and transmit the signal via an optical fiber, allowing electronic components to be placed out of pile, away from radiation. However, the photon collection efficiency of current prototypes is only $\eta \approx 1.78 \times 10^{-7}$, limiting detector sensitivity [2]. This work presents a dedicated Monte Carlo simulation code, written in C, that estimates the impact of a new OND geometry—combining a hemispherical fissile deposit and a parabolic mirror—on photon collection efficiency, while accounting for the thermal radiation generated at high temperatures. The code comprises three coupled Monte Carlo loops: heavy-ion transport in gas (using polynomial moderation laws from COSICAF), plasma-photon propagation by ray tracing, and thermal wall-radiation modeling at 600 °C. A parametric study identified the negligible impact of the focal length of the parabolic mirror around the geometrically calculated value and quantified the impact of the reflective surfaces, and gas density. The proposed geometry achieves $\eta = 5.4 \times 10^{-6}$, a factor of 30 improvement over to current prototypes. These results call for progressive experimental validation, from out-of-reactor thermal characterization to in-reactor testing.

A Validated GEANT4 Model of a Dual-HPGe γ–γ Coincidence Spectrometer for Detection Sensitivity Evaluation (#1900)

Thomas C. Stokes[1,2], Matthew Goodwin[1], Mark Jackson[1], Andrew Boston[2]

[1] AWE Nuclear Security Technologies, Aldermaston, UK; [2] The Oliver Lodge Laboratory, The University of Liverpool, Liverpool, UK

Abstract

Gamma-gamma (γ-γ) coincidence is an advanced radiometric detection technique that has been widely demonstrated to reduce detection limits for many radionuclides in a variety of sample types and applications. The superior selectivity of γ-γ coincidence spectrometry in comparison to traditional single detector analysis, reduces the sensitivity of detection limits to changes in the activity of impurity radionuclides. This is particularly true in the case of impurities that do not emit coincident gamma photons (e.g. ^{137}Cs). In this work, a GEANT4 model of a dual high-purity germanium γ-γ coincidence system has been developed and validated against experimental measurements. Additionally, a method to generate modelled time-stamped list mode (T-List) data is presented and demonstrated using long and short-lived radionuclides. By processing the modelled T-List data, the effect on the detection limit for an analyte of interest in the presence of an impurity radionuclide can be studied. These preliminary results demonstrate how the detection limit of ^{134}Cs shows no measurable dependence on the activity of ^{137}Cs over the simulated range of 0.2-100 kBq. Future work will seek to investigate the influencing factors on detection limits for coincidence spectrometry as well as demonstrate the use of γ-γ coincidence alongside radiochemical separations to accelerate analytical timelines.

Abstract

Quantum imaging with annihilation photons has recently emerged as a promising imaging modality [1, 2]. Positron annihilation photons are correlated particles, carrying the same energy of 511 keV and opposite momenta. The technique relies on coincidence measurements of the annihilation photons' energies and positions, with an object placed in front of one of the detectors. As a result, a ghost image of the object forms in the other detector, and the real image is enhanced by background noise reduction, since the noise lacks the photons' correlations. In this work, we explore the limits of the modality for background noise reduction via Geant4 simulations. The coincidence measurements are simulated for an experimental setup encompassing two segmented scintillating detectors, comprised of 64 Gadolinium Aluminum Gallium Garnet (GAGG) crystals and assembled into an 8x8 square matrix with 3.2 mm pitch [3]. We have found that quantum imaging outperforms classical gamma transmission imaging by retaining the contrast-to-noise ratio (CNR) of noiseless conditions regardless of the background noise intensity. We have also tested the penetrative aspect of annihilation gamma rays, exploring the possibility of detecting attenuation variations in optically dense, high-Z materials.

This research was undertaken with the assistance of resources from the Australian National Computer Infrastructure (NCI) supercomputer cluster.

Abstract

To progress synchrotron-based, spatially fractionated X-ray radiotherapy towards clinical trials, the efficacy of clinically relevant treatment fields must be assessed. In this paper, we present the development and validation of a Geant4 model for human-relevant broad beam (BB) and minibeam radiotherapy (MBRT) treatment fields (up to 7 x 7 cm^2) in an experimental hutch located 140m from the synchrotron source at the Imaging and Medical Beamline at the ANSTO Australian Synchrotron. Both broad beam and MBRT treatment fields were modelled for different beam energies and field sizes, with two minibeam fields of different peak spacing investigated. BB and MBRT (peak and valley) depth doses were investigated up to 7cm in a solid water phantom. There was excellent agreement in broad beam percentage depth dose curves (within 4%) as well as the minibeam peak depth dose curves (within 6%), with the model and experimental results agreeing within combined uncertainty for all depths and configurations investigated. There was good agreement in valley dose when comparing EBT-XD Gafchromic film to the model with most results within 10% and within uncertainty. However, there was disagreement between the valley dose measured by the microdiamond detector and the Geant4 model up to 15%. This model will be useful for further MBRT experiments performed at IMBL, with future work validating this model for 3D printed patient volumes.

SimpleMC: A Simple and Flexible Monte Carlo Simulation Tool for Timepix Detectors (#2518)

Chia-Wei Huang[1], Jaroslav Čeřovský[1], Štěpán Malec[1], Vladimír Linhart[1], Kamilla Sabirzyanova[2], Karolína Melovská[2], Eliška Soharová[2]

[1] Czech Technical University in Prague, Faculty of Nuclear Sciences and Physical Engineering, Prague, Czech Republic; [2] ADVACAM, Prague, Czech Republic

This project is co-financed by the Technology Agency of the Czech Republic (TACR) within the SIGMA Program, project no. TQ15000215.

Abstract

Timepix type pixel detectors enable event-by-event radiation measurements [1], but classification of mixed fields remains challenging due to scarce labeled data and detector dependent effects. We present SimpleMC, an Allpix^2 [2, 3] based framework for generating realistic synthetic Timepix datasets by combining Monte Carlo transport simulation with detector response modeling and data driven refinement. Photon and electron benchmarks are improved using two complementary approaches: a tuned digitizer and a simplified Gaussian smearing model. These approaches enhance agreement with calibration and spectral measurements. For proton and alpha particles, generative models are used to bridge the sim-to-real gap, including Contrastive Unpaired Translation (CUT) and Conditional Diffusion Denoising Probabilistic Models (CDDPM). The models are trained to map simulated cluster representations to experimental-like responses. CDDPM outperorms CUT in capturing experimental variability and improving generalization to unseen geometries and irradiation conditions. The framework is evaluated across photons, electrons, and heavy charged particles, showing good agreement in both energy related observables and cluster morphology. Additional experimental datasets from complex radiation environments, including fusion relevant tokamak conditions, are collected for future validation. SimpleMC provides a flexible framework for realistic synthetic data generation, supporting detector characterization and the development of advanced simulation based analysis tools. It will be further developed into a user-friendly toolkit with documentation for the broader radiation detection community.

Abstract
The ClearMind collaboration is developing a next-generation Time-of-Flight PET detector aiming at sub-100 ps coincidence resolving time, high detection efficiency and precise spatial resolution. This presentation discusses the modeling of the ClearMind gamma detector, made of crystal with direct photocathode deposition and microchannel plate (MCP) electron multiplication. The simulation model uses Geant4 software to simulate gamma interactions within the crystal and the propagation of optical photons. Photoelectron generation, multiplication and signal processing are described through a parametrized simulation. This model is crutial for both understanding and optimizing the ClearMind prototype and for development of machine learning-based reconstruction algorithms. To

validate the model, we compare simulation results with experimental measurments PbF_2, $PbWO_4$, BaF_2 and LYSO crystals assembled with the Incom HRPPD MCP-PMT in a conventional configuration. We also explore various factors contributing to the detector's time resolution, including photon collection efficiency, photocathode efficiency, single-photon time resolution and signal pile-up effects. Additionally, we investigated new estimators using deep learning models trained on simulation for time reconstruction and event-by-event associated uncertainty estimation enabling us to select the most precise events. The preliminary results show a time resolution below 100 ps.

3-D simulation of carrier transport and signal formation in silicon detectors for charged particle identification (#2910)

Andrea Castoldi[1,2], Chiara Guazzoni[1,2], Filippo Buda[1]

[1] Politecnico di Milano, DEIB, Milano, Italy; [2] INFN, Sezione di Milano, Milano, Italy

Abstract

Fast simulation of carrier generation, transport and signal formation is a powerful tool for the optimization of segmented detector arrays targeted to charged particle identification in nuclear physics experiments. A custom numerical tool for the self-consistent computation of the electron-hole dynamics has been used to study ion tracks in silicon and non-silicon detectors. The code includes the effect of thermal diffusion and Coulomb interaction among the mobile carriers in a microscopic fashion, essential for the correct simulation of high-density ionization tracks in which plasma-like effects (field screening, transient distortions, collection slowdown, and marked nonlinearities) become significant, like in the case of heavy ion interactions. We addressed the challenging case of intermediate mass fragments stopping in the typically few hundred microns of the first detection layer of a telescope configuration, where particle identification critically relies on pulse-shape analysis. Simulations were carried out for several ions - from Li6 to Na22 - impinging on a silicon detector with energies up to the punch-through condition. We studied the impact of the relevant properties of detector and preamplifier response and of the effectiveness of different pulse-shape algorithms to assess the minimum energy threshold and the achievable resolution in charged particle separation in mass (A) and atomic number (Z).

Abstract

High-melting-point oxide scintillators are key materials for radiation imaging and harsh-environment radiation detection, but their scaling is limited by iridium crucibles, melt contamination, and composition fluctuation. We report crucible-free growth and scaling of Ce:LYSO and Y_2O_3 scintillators using the oxide crystal growth from cold crucible (OCCC) method. In OCCC growth, the oxide melt is directly heated by high-frequency induction and retained by a self-formed solidified raw-material layer in a water-cooled copper basket. Ce:LYSO was grown in air, and EPMA showed host-cation segregation coefficients close to unity for Lu, Y, and Si. The straight-body region exhibited light-output variation within ±20%, with a maximum light output of approximately 16,000 photons/MeV under ^{137}Cs 662-keV excitation. Most importantly, an ultrahigh-melting-point Y_2O_3 scintillator was successfully grown to a 3-inch diameter by OCCC, and polished Y_2O_3 samples exhibited transparent appearance and a clear scintillation response under ^{137}Cs excitation. The OCCC method is a promising platform for scaling high-melting-point oxide scintillators without precious-metal crucibles.

NSS-07-02

$Cs_3Cu_2I_5$ Single Crystals Grown with Oleic- and Formic-Acid-Assisted Additives: Effects on Crystal Quality and Scintillation Properties (#2527)

Bhavika Bansal, Vivek Anand, Anil K. Gourishetty

Indian Institute of Technology Roorkee, Department of Physics, Roorkee, India

Abstract

$Cs_3Cu_2I_5$ single crystals were grown at room temperature via a solvent evaporation method using two organic acid additives: oleic acid (OA) and formic acid (FA), and their effects on crystal quality and scintillation performance were systematically investigated. X-ray photoelectron spectroscopy confirmed the absence of Cu^{2+} features in both samples, demonstrating that organic acid additives effectively suppress Cu^{+} oxidation during growth. Single-crystal X-ray diffraction and rocking curve analysis revealed that formic-acid-assisted crystals exhibit superior crystalline quality, with a narrower rocking-curve FWHM of 0.009° compared to 0.016° for OA-assisted crystals. Scintillation measurements using a ^{137}Cs γ-ray source (662 keV) coupled to a SiPM photosensor showed an improved energy resolution of 5.4% for formic-acid-grown crystals versus 5.8% for OA-grown crystals. The enhanced performance of

FA-assisted crystals is attributed to formic acid's ability to regulate iodide ion availability through slow reaction with I^{3-} species, reducing the crystallization rate and extending the metastable growth regime, thereby suppressing defect formation. In contrast, the long-chain nature of oleic acid promotes residual ligand incorporation and non-uniform solvent evaporation, slightly degrading optical transparency and crystallinity

NSS-07-03

Novel $Cs_3Cu_2I_5$:Tl Scintillator Films for X-ray Imaging (#2891)

Lakshmi Soundara Pandian, Jun Wang, Govinda Adhikari, Edgar van Loef, Jarek Glodo, Vivek Nagarkar

Radiation Monitoring Devices, Inc., Imaging Sensors and Applications, Watertown, USA

Abstract

Tl-doped cesium copper iodide ($Cs_3Cu_2I_5$:Tl, CCI:Tl) has emerged as a promising scintillator for medical imaging, offering higher light yield than the long-established CsI:Tl while remaining non-hygroscopic and lead free. Its emission (445–500 nm) matches the quantum efficiency of CCD, CMOS, and flat panel readouts, making it an excellent choice as a converter for advanced X-ray detectors. Detectors based on CCI:Tl have potential for providing dose efficiency in medical applications including digital mammography, radiography, and cone-beam CT. The high brightness of CCI:Tl will enable their use in high framerate or otherwise light starved applications in both medical and industrial fields.

We report on the development of polycrystalline CCI:Tl scintillating films grown by hot wall evaporation (HWE), a technique previously used to produce columnar, low stress CsI:Tl films and extended here to the ternary CCI system. CCI crystals were first grown and then used as the source for evaporation. Material quality was characterized by SEM and EDX. EDX confirms stoichiometric Cs:Cu:I ratio of 3:2:5. Scintillation properties were measured under gamma and X-ray excitation, including pulse-height spectra, emission, light yield relative to CsI:Tl, scintillation decay time, and afterglow. X-ray imaging performance was evaluated through quantification of contrast transfer function (CTF(f)) and measurements of modulation transfer function (MTF(f)) using a slit method. with films demonstrating resolution 5 lp/mm at 70 kVp for thickness in excess of 150µm. The results indicate structured growth and demonstrate that HWE grown CCI:Tl films offer a viable, potentially higher luminosity alternative to CsI:Tl for indirect medical-imaging detection while also revealing the deposition parameters that govern film morphology and scintillation response. Results from both crystals and films and applications of CCI:Tl films will be presented.

NSS-07-04

Growth and Pellet Fabrication of 2D Perovskite Scintillator Radiation Detectors (#2585)

Amy J. Dickinson[1], Carol Crean[1], Joydip Ghosh[2], Phasit Petisiwaveth[1,3], Paul Sellin[1]

[1] University of Surrey, School of Mathematics and Physics, Guildford, UK; [2] University of Oxford, Department of Chemistry, Oxford, UK; [3] University of Wollongong, School of Physics, Wollongong, Australia

Abstract

Two-dimensional (2D) metal halide perovskites have emerged as promising scintillator materials for radiation detection due to their high x-ray and gamma-ray absorption coefficients, high light yields, and fast scintillation decay times. Their structural flexibility enables precise tuning of optical and scintillation properties through variation of the organic spacer, halide composition, and dopant incorporation [1]. This work presents the synthesis, optical characterisation, and pellet fabrication of several 2D perovskite scintillators, including the Ruddlesden-Popper (RP) phase materials $(BA)_2PbBr_4$ and $(PEA)_2PbBr_4$, and the Dion-Jacobson (DJ) phase material $(TMPDA)PbBr_4$. Crystals were synthesised using a slow-cooling solution growth method and subsequently processed into pellets using a cold-pressing technique to increase thickness while improving uniformity and reproducibility. The effects of manganese and rubidium doping in $(BA)_2PbBr_4$ were also investigated, demonstrating enhanced light yield and tuneable emission behaviour. Under x-ray excitation, $(PEA)_2PbBr_4$ exhibited a light yield exceeding that of LYSO, while all investigated materials demonstrated promising gamma-ray scintillation responses with resolvable peaks. These results highlight the strong potential of 2D perovskite scintillators for next-generation radiation detection technologies.

Enhanced Light Outputs in Cs_2ZnCl_4 Single Crystals via Hydrothermal Purification and Cd Doping (#2781)

Yuzhe Wu, Mingxue Deng, Shaohan Wang, Jie Ma, Tong Wu, Junfeng Chen

Shanghai Institute of Ceramics, Chinese Academy of Sciences, State Key Laboratory of Functional Crystals and Devices, Shanghai, China

This work was supported by the National Key Research and Development Program of China (2023YFA1606300), the National Natural Science Foundation of China (12405227).

Abstract

Cs_2ZnCl_4 single crystals exhibit ultrafast cross-luminescence and show great potential for high-repetition-rate and fast timing radiation detection areas. However, their light output is severely limited by synthesis-induced impurities and intrinsic defects. To address this bottleneck, this work systematically investigates two parallel strategies: hydrothermal purification and Cd doping. High optical-quality single crystals were grown via the vertical Bridgman method using hydrothermally purified method, followed by systematic optical transmittance, luminescence, and absolute light output characterizations. The results demonstrate that hydrothermal purification effectively eliminates heavy metal impurities in the precursors, significantly enhancing the light output (LO) from 680 ph/MeV to 1078 ph/MeV (a 58.5% increase) while fully preserving the crystal's ultrafast decay constant of 1.76 ns. Furthermore, Cd doping increases the light output to 3689 ph/MeV, representing an enhancement of 126.6%. This study provides two effective strategies for enhancing the light output of ultrafast halide light-emitting materials.

Scintillation Properties of Ce^{3+}-, Pr^{3+}-, and Eu^{2+}-Doped LiCl, LiBr, and LiI Single Crystals (#2238)

Jarek Glodo, Edgar van Loef, Lakshmi Soundara Pandian

Radiation Monitoring Devices, Inc., Watertown, USA

Abstract

Lithium-rich scintillators are widely used to detect thermal neutrons, with Eu-doped lithium iodide (LiI:Eu) serving as the long-standing benchmark. LiI:Eu, however, has high gamma sensitivity, slow scintillation decay, and limited ability to distinguish neutrons from gamma rays. As a result, we have shifted our focus towards the lighter binary lithium halides, such as lithium chloride (LiCl) and lithium bromide (LiBr), which offer intrinsically lower gamma sensitivity. We also investigated Ce^{3+} and Pr^{3+} with the goal of evaluating their ability for fast *d-f* type emission and neutron-gamma discrimination.

Single crystals were grown by the vertical Bridgman method and characterized by X-ray luminescence, light yield, decay time, and neutron response using a moderated Am/Be source. Initial results show that LiBr:Ce delivers a clear thermal-neutron peak at 3.1 MeVee with a light yield of 7,300 ph/n (comparable to GS20) and pulse-shape discrimination capability. Full data and comparison across all dopant-host combinations will be presented.

NSS-07-07

Characterising ZnSe(Al,O) for Real-Time Sr-90 Beta Spectroscopy

(#2965)

Arjana Kolnikaj, Kelum A.A. Gamage, Olaoluwa R. Popoola

University of Glasgow, James Watt School of Engineering, Glasgow, UK

The author acknowledges the School of Physics and Astronomy at the University of Glasgow for access to laboratory facilities. Special thanks are given to Mx Thomas Queen for access to the nuclear laboratory, and to Dr Graham Gibson for access to the laser system and guidance on the Brewster-angle refractive-index measurement.

Abstract

ZnSe(Al,O) is a promising scintillator for compact beta spectroscopy, but its detector-relevant properties are poorly documented and strongly dependent on dopant composition, growth quality, and optical transport. This work experimentally characterises a commercially supplied ZnSe(Al,O) crystal intended for use in a silicon photomultiplier-coupled beta detector for strontium-90 monitoring. The crystal measured 42 mm in diameter and 2.1 mm in thickness. Scanning electron microscopy with energy-dispersive X-ray spectroscopy confirmed a zinc selenide composition with aluminium and oxygen impurities, giving measured atomic abundances of 49.2% zinc, 46.1% selenium, 3.50% oxygen, and 1.2% aluminium. The measured density was 5.31 g cm^−3, and the refractive index determined using a Brewster-angle method was 2.475. Scintillation waveforms were recorded under strontium-90/yttrium-90 beta irradiation using silicon photomultiplier readout and analysed to extract charge spectra and decay behaviour. The light yield was estimated to be approximately 7.8 × 10^4 photons MeV^−1, while the decay constant was measured as 9.41 us, with a waveform-to-waveform standard deviation of 1.1 us. These values are broadly consistent with the range reported for zinc-selenide-based scintillators, while providing a single experimentally derived parameter set for this specific ZnSe(Al,O) sample. The results support the suitability of ZnSe(Al,O) for silicon photomultiplier-based beta spectroscopy and provide material inputs required for improved detector modelling, optical design, and future development of compact detectors for environmental strontium-90 monitoring.

This work is performed in the framework of the Crystal Clear Collaboration (CCC) and the European Pathfinder Open project UNICORN (GA 101098649). Additional support was provided by the Grant Agency of the Czech Technical University in Prague, Grant Number SGS24/145/OHK4/3T/14.

Abstract

Efficient detection of fast ultraviolet scintillation is essential for the next generation of high-speed radiation detectors. We investigate $CsPbX_3$ nanocrystals as a versatile wavelength-shifting platform, leveraging their sub-nanosecond response times and tunable bandgaps to match the peak sensitivity of standard photodetectors. As a proof-of-concept, using radioluminescence measurements, we characterize the conversion of scintillation light from a LYSO:Ce reference crystal by $CsPbBr_3$ nanocrystal layers and polymer-based nanocomposites. It has been observed that concentrated drop-cast layers perform better than nanocomposites and achieve total extinction of the broad scintillation peak of LYSO:Ce at 430 nm, shifting it to 535 nm, corresponding to the nanocrystal emission. Rigorous validation tests confirm that the observed green emission is a product of wavelength-shifting rather than a result of direct nanocrystal excitation or spectral attenuation of the primary light. This performance establishes a foundation for modular wavelength-shifting interfaces that can be tailored to various scintillators and radiators, including BaF_2 (cross-luminescence), CeF_3, and PbF_2 (Cherenkov light).

This work was supported by the European XFEL GmbH in the DSSC project framework.

Abstract

The DEPFET Sensor with Signal Compression (DSSC) is a 1-megapixel, 2D X-ray detector designed for the European XFEL, capable of operating at MHz frame rates. This work presents the characterization results of the second-generation DSSC focal-plane modules (FPMs), which incorporate active DEPFET sensors to improve dynamic range and performance compared to the first-generation mini-SDD-based camera. Each FPM—the smallest independent unit of the camera—comprises two sensors read by eight ASICs and underwent rigorous geometric characterization, with sensor-to-sensor systematic deviation of 32.9 ± 68.9 µm and −48.6 ± 66.9 µm in the x- and y-direction, respectively. Functional tests were run under vacuum at 18°C. Key metrics demonstrated excellent reproducibility of prototype characterization, with tight distributions in sensitivity (199.4 ± 5.4 eV/ADU), equivalent-noise charge (23.2 ± 1.2 e- rms), first gain-compression energy (74.9 ± 4.3 keV) and in-pixel leakage current (1.3 ± 0.3 pA/pixel). The results validate the reliability of the DEPFET FPMs for integration into the 1-megapixel camera, ensuring uniform performance.

Abstract

The fourth generation of synchrotron light sources brings unprecedented brightness to the experimental stations of the x-ray science community. As light sources improve their performance, detector instrumentation requirements become more demanding. Among these, readout electronics should be capable of achieving zero dead-time, handling an inter-bunch spacing of just a few nanoseconds, and including a digital backend able to deal with the expected data stream. In this context, a prototype readout channel has been developed in a commercial 65 nm CMOS technology and assembled in a 16-pixel matrix, named pFREYA16. Each pixel features a low-noise Charge-Sensitive Amplifier, a semi-Gaussian unipolar RC-CR shaper with four selectable peaking times, a pseudo-differential discrimination chain to enable zero-suppression, and an A/D chain with a differential S/H and a differential 10-bit SAR ADC, along with a basic digital backend to shift data out and configure the matrix. The prototype has been fully characterised at each stage of the signal processing chain. It exhibits a linear input-output transfer characteristic over a full-well capacity of 256 photons at 5, 9, 15, and 25 keV, single-photon resolution with a measured ENC of 380 e- rms at 9 keV at a frame rate of 1 MHz, and a power consumption of approximately 220 uW per pixel.

DIANA: An LGAD-Based Architecture for Soft X-Ray Detection (#2095)

Francesca Capocasa[1], Abdul Rumaiz[2], Giovanni Pinaroli[1], Gabriele Giacomini[1], Anthony J. Kuczewski[2], David P. Siddons[2], Gabriella Carini[3]

[1] Brookhaven National Laboratory, Instrumentation, Upton, USA; [2] Brookhaven National Laboratory, NSLS II, Upton, USA; [3] Brookhaven National Laboratory, Discovery Technology Directorate, Upton, USA

Abstract

Soft X-ray detection is essential for synchrotron and free-electron laser science, but existing detector technologies remain limited in quantum efficiency, signal-to-noise ratio, and readout performance at low photon energies. In this work, we present DIANA, a Low-Gain Avalanche Diode (LGAD)-based detector architecture optimized for soft X-ray applications. The device employs a p-type entrance window for high transparency and places the gain layer on the readout side, allowing charge carriers generated near the entrance surface to drift through the full silicon thickness before undergoing controlled internal amplification. An additional n-type buffer layer is introduced between the gain layer and segmented readout electrodes to mitigate electric field non-uniformities and improve stability. TCAD simulations and first prototype fabrication at Brookhaven National Laboratory demonstrate stable operation above full depletion and confirm the effectiveness of the buffer layer in shaping the electric field. Electrical characterization shows clear charge multiplication with gains up to approximately 3, while spectroscopic measurements demonstrate stable and nearly energy-independent amplification across the investigated photon-energy range. These results validate the DIANA concept as a promising candidate for next-generation soft X-ray detectors.

Abstract

The upgrade of synchrotron facilities, such as Swiss Light Source 2.0 (SLS 2.0), will provide significantly higher brilliance and photon flux than current-generation sources. These operating conditions will exceed the count-rate capability of many existing single-photon-counting detectors. Although higher photon flux improves acquisition capability, synchrotron experiments still often rely on detecting weak features where only a few photons contain

important information. Preserving sensitivity while operating at very high photon flux therefore becomes a major challenge. To address these limitations, Matterhorn, a single photon counting hybrid pixel detector, is developed at the Paul Scherrer Institute for future high-flux synchrotron experiments. The detector implements a multi-threshold photon-counting architecture with four independently adjustable thresholds in each pixel to improve count-rate performance under high-flux condi- tions. The detector targets count rate up to 20 Mcounts/pixel/s through the implementation of multi-threshold circuitry in each pixel. The ASIC consists of a 256 × 256 pixel matrix with a pixel pitch of 75 × 75 µm 2 and is implemented in UMC 110 nm technology. Single-chip assemblies (i.e. a single chip bump- bonded to a single-chip sensor) are characterized using both a laboratory X-ray source and measurements at the SLS beamline. Preliminary measurements demonstrate stable operation of the full-size ASIC and reproduce the performance from the prototype studies. This contribution presents the current characterization status and summarizes the main performance results obtained so far, while a more detailed discussion of the detector architecture will be presented in a separate contribution.

Abstract

In X-Ray Fluorescence Microscopy, where the analyses can take up to several hours, optimizing the solid angle of the spectrometer is critical. Moreover, the use of multichannel spectrometers is now a necessity due to the high throughput required from the incread brilliance achieved by modern, 4th generation synchrotrons.

ORBIS is a 16-channel monolithic SDD array optimized for backscattering configurations, with a geometry that can guarantee an uncollimated total solid angle coverage of 2.35 sr while ensuring uniform irradiation of all the pixels. The project, supported by Ruhr University Bochum (RUB) and Deutsches Elektronen-Synchrotron (DESY) aims to develop a novel, vacuum compatible spectrometer to be used for biological experiments.

A preliminary characterization of the SDD array shows promising results, with FWHM resolutions as low as 131 eV measured at the Mn-kα line at 800 ns peaking time, and 171 eV FWHM at 32 ns peaking time.

The first tests in P06 beamline are planned in June 2026, during which the instrument performance will be evaluated. The results of this campaign will be reported at the conference.

Abstract

The evolving requirements of X-ray Free Electron Laser (XFEL) applications in terms of speed, dynamic range, and noise motivate the development of new X-ray pixel detectors. The next generation of detectors must provide a high dynamic range while maintaining low-noise performance to ensure single-photon detection at low energies. In this work, we present a front-end architecture employing a Charge Sensitive Amplifier (CSA) with predictive gain switching and a Flip-Capacitor filter. The CSA is designed to achieve both a high dynamic range up to 10^4 photons and single-photon resolution by means of active gain control. The novel predictive gain switching circuit sets the optimal gain by measuring the time required for the CSA output signal to exceed a fixed threshold. The trapezoidal filter, by reducing the electronic noise, enables single-photon resolution at low energies when the CSA operates in its highest gain configuration. A dedicated voltage-to-current converter has been designed to couple the CSA and the filter. The proposed front-end is implemented in 65 nm CMOS technology, and preliminary characterization has been performed to evaluate gain switching and noise performance. The ASIC has been coupled to a Silicon Drift Detector (SDD), and an Equivalent Noise Charge of 35 e^- has been measured. Further measurements, including tests with a mini-SDD, are planned. This front-end architecture will be proposed for the XSTREAM (Xray detector System with high-Throughput REadout Architecture and Modularity) Pathfinder.

Abstract

We performed the mesh experiment to map the charge collection function of hexagonal DEPFET pixels of the DSSC camera, a 1024x1024 hybrid pixel detector targeted at soft X-ray imaging experiments at the European XFEL with stringent requirements on noise, speed and dynamic range. With a read noise of few electrons rms, the measurement of the pixel charge collection function and its correlation to pixel layout and operating conditions are essential to assess the spectroscopic performance of the camera and detect possible optimizations. The obtained virtual scan of the hexagonal pixel of one DSSC sensor (256x128 pixels) highlights a non-uniform charge collection that can affect the camera spectroscopic performance, proving the effectiveness of this technique to optimize the performance of large, low-noise detectors.

Abstract

High-resolution particle detectors based on microchannel plates (MCPs) provide unique capabilities for applications requiring detection of photons, electrons, ions, and neutrons with high spatial and temporal resolution. Recent advances in readout technologies have substantially increased the counting-rate capabilities of these detectors, with rates exceeding 10^8 particles/s/cm². However, experiments with even higher incident fluxes remain limited by the number of particles that MCP detectors can process.

In some high-flux applications, only a small fraction of the incident particles needs to be recorded, while the total flux can be extremely high. In such cases, fast gating of the detector can prevent unnecessary charge extraction and allow MCP-based detectors to operate under otherwise unsustainable flux conditions. For soft X-ray, gamma photons, electron, neutron and ion detection, the primary particle conversion occurs at the front surface of the MCP itself. In this case, the MCP itself must be gated directly, which is challenging because of the MCP's large capacitance and high operating bias.

In this paper, we present results from gated MCP detectors that can be switched on and off on a time scale of approximately 5 ns. We demonstrate this capability using an MCP detector with a Timepix readout, selectively detecting chosen synchrotron pulses while suppressing detection of the remaining bunches. Without gating, the detector is oversaturated and cannot operate under the same incident flux. This gating approach is applicable to a broad range of MCP readout configurations, not only Timepix-based systems, and enables high-resolution MCP detectors to be used in applications where the total input flux would otherwise exceed their sustainable operating range.

Abstract

A system comprising sixteen polyvinyl toluene (PVT) scintillators is under development at the Nuclear Measurements Laboratory (CEA IRESNE) for the passive nondestructive assay of alpha-contaminated waste drums. Although PVT scintillators offer a low-cost alternative to ^{3}He counters, their sensitivity to gamma rays and scattering cross-talk restricts the use of traditional multiplicity equations for determining spontaneous fission rates. Machine learning methods provide a viable solution to this inverse problem but require extensive training datasets, necessitating a reliable, experimentally validated numerical model. Therefore, a novel calculation scheme utilizing the FIFRELIN and PHITS Monte Carlo codes is introduced. This framework generates and transports prompt fission particles, extracting raw time-of-flight and energy deposition data. The resulting files are subsequently processed using ROOT scripts to model the detectors' response. Specifically, the energy resolution function implemented in the simulation is derived from a ^{60}Co source measurement, utilizing parameters adjusted to align the simulated and experimental spectra. The full framework demonstrates good agreement with the measurement of ^{252}Cf doubles and triples counts, enabling the generation of training data for regression models capable of accurately predicting spontaneous fission rates across various measured mock drum configurations.

Abstract

The ^{6}Li-glass (GS20) Scintillator-based Anger cameras have been used for single-crystal neutron diffractometry. To expand their applications for more neutron-scattering instruments and Boron Neutron Capture Therapy (BNCT) with a neutron flux~10^{9} n/s/cm^{2}, there are urgent needs to improve the neutron detection efficiency, light yield, and neutron-gamma discrimination ratio (NGD ratio, or efficiency ratio), and to reduce the light decay lifetime of the neutron scintillator. We have developed Eu^{2+}:CaF_2/^{6}LiF eutectic scintillators to potentially replace the GS20 in neutron Anger cameras. In this work, we show our further endeavors in i). enhancing light yield of the eutectics in casting method; ii). improving transparency and uniformity of the eutectics in oriented growth; iii). reducing the light decay lifetime to about 4 ns via Pr^{3+} doping; iv). the enhancement in the NGD ratio using an optimized multi-layer graph filter under a self-supervised learning framework. Therefore, future Eu:CaF_2/^{6}LiF eutectic neutron scintillators are expected to find wider applications not only in neutron scattering and BNCT, but also in nuclear power plants and homeland security.

Abstract

Accurate assessment of plutonium content during pyroprocessing is needed to enhance the proliferation resistance. Matrix isotopic heterogeneity, source non-uniformity, and high gamma-ray emission rate prevent the application of traditional non-destructive assay (NDA) systems and methods. We aim to develop a novel NDA system that can withstand pyroprocessing harsh environments and have consistent sensitivity and accuracy despite different fuel form factors. The proposed NDA system encompasses two system modules, a boron-coated-straw (BCS) multiplicity module and a 3D boron-coated-straw detector array (3D-BCSDA) tomography module. The multiplicity module performs multiplicity counting and provides assay observables, whereas the tomographic module reduces systematic biases by enabling geometry-aware corrections. In this work, we report the development of the multiplicity module and the 3D-BCSDA tomography module. The multiplicity module consists of six 64-straw BCS panels, with a measured neutron detection efficiency of 12.4% and die-away time of 42 μs. The tomography module is a moderated array incorporating thirty one-meter-long boron-coated straws with double-sided readout. Time delay lines and charge sharing have been implemented to enable 3D localization of the neutron interaction event. We will begin experimental testing with laboratory sources at UIUC and plutonium sources at INL to assess the system’s accuracy in real-world conditions, supporting the integration of tomographic imaging with neutron multiplicity counting for bulk plutonium assay.

This work was supported by the REALPATH project (Italian MUR), grant n. FISA-2022-00779

Abstract

The REALPATH detector and readout platform is a pixilated scintillation detector developed for prompt gamma imaging in proton therapy. Prompt gamma imaging aims to provide online verification of proton range via the position-sensitive detection of prompt gamma rays emitted during proton treatment. Due to the high fluence of modern medical proton accelerators, the detector is designed to cope with rates of up to 1 Mcps per pixel across 512 pixels. At the same time, good spectroscopic performance at high energies in the range of 3 MeV to 6 MeV is beneficial for neutron background rejection and prompt-gamma emission analysis. To address these requirements, each LYSO pixel features an independent SiPM readout, implemented with the custom SITH (spectroscopy imaging timing hadrontherapy) ASIC. In this work, we present the experimental characterization of the first 64-channel detector module. Using a ^{137}Cs source, we measured an average resolution of 8.5% at 662 keV for all pixels at low rates. The high source activity allowed us to characterize the detector up to 1.9 Mcps input count rate per channel. The high-energy performance was tested with a ^{241}Am-Be source that provides gamma rays of 4.44 MeV. By applying a light-sharing correction and combining data from coincident events across multiple pixels, we achieved an energy resolution of 4.8% at the 4.44 MeV full-energy peak. With these characteristics, the detector may also be suited for applications beyond prompt gamma imaging that require position-resolved high-rate gamma spectroscopy.

Ratiometric Alpha-Particle and Gamma-Ray Imaging with a Ligand-Stabilized $CsPbBr_3$Perovskite-Nanoparticle Coating on a 4.8-Megapixel Stacked CMOS Sensor (#2798)

Abstract

Conventional alpha/gamma instruments often use bulk scintillators coupled to photomultiplier or silicon-photomultiplier pulse processing, or hybrid pixel detectors optimized for timing or deposited-energy readout; compact megapixel imaging with ratiometric particle-type contrast remains less developed. A monolithic alternative is demonstrated by spin-coating a 10-μm film of ligand-stabilized $CsPbBr_3$ perovskite nanoparticles (PNCs) onto a vertically stacked 4.8-megapixel complementary metal-oxide-semiconductor (CMOS) image sensor containing three photodiodes per pixel. Gamma-ray interactions in the PNC layer generate green scintillation photons that are registered differentially by the top, middle, and bottom photodiodes, whereas alpha particles deposit energy primarily in the top photodiode layer. Comparing these spatially registered photodiode responses with cluster amplitude and event footprint yields ratiometric single-frame alpha/gamma signatures without an external scintillator/photomultiplier timing chain. Radiation-induced events were extracted from full-frame readout as temporally nonpersistent, 8-connected pixel clusters. Relative to the uncoated sensor, the coated detector increased gamma-candidate event yield by 10^3-10^4 in Am-241, Co-57, and Ac-225 measurements. Gamma-candidate clusters exhibited median signal-to-noise ratios of 10.9-11.0 and a median footprint of one pixel. In unfiltered Ac-225 free-path measurements, the coated sensor preserved the direct alpha-particle response while adding gamma sensitivity. These results establish a spin-coated PNC/three-photodiode stacked CMOS architecture for compact, spatially resolved, ratiometric alpha/gamma imaging.

Evolution of ZnS:Ag/^{6}LiF wavelength shifting fibre detectors from flat to tilted geometry (#2905)

Giacomo Mauri[1], Jeff G. Sykora[1], Sarah E. Mann[1], Erik M. Schooneveld[1], Nigel J. Rhodes[1]

[1] STFC, ISIS, Harwell Campus, UK; [2] STFC/ISIS, Didcot, UK

Abstract

Scintillator-based neutron detectors have been developed at ISIS for over three decades, with ongoing research and development focused on enhancing performance and meeting increasingly demanding instrument requirements. The Endeavour programme places new demands on detector technology, particularly in achieving large-area coverage, high spatial resolution, and high counting-rate capability.

Conventional WLSF detectors are built from stacked flat scintillator screens interleaved with fibre planes. Achieving high neutron efficiency (~80% at 1.8 Å) requires four scintillator layers and two fibre planes. This work presents a novel approach to the design and manufacture of ZnS:Ag/^{6}LiF wavelength-shifting fibre (WLSF) detectors, with the potential to significantly improve both performance and cost-efficiency for next-generation systems.

This concept instead exploits the increase in neutron path length by tilting the scintillator relative to the incident beam. A V-shaped strip geometry is introduced, where the angle can be tuned to control detection efficiency and fibre spacing. This design also provides optical isolation between strips, enabling parallel signal processing for neutron event identification, which significantly reduces the detector dead time.A first linear position-sensitive detector prototype was developed featuring four regions with varying fibre pitches and tilt angles. This was followed by a 2D position-sensitive detector based on the same principle. The designs and performance results from tests on ISIS instruments are presented, along with a discussion of simplified manufacturing and reduced costs.

Overall, these advancements enhance detector capability and support the continued evolution of the ISIS science programme, enabling future instrument upgrades.

This work was supported by NASA (Proposal No. 22-APRA22-0026)

Abstract

We present NSX1, a very-low-power 64-channel front-end ASIC developed for large-area broadband-energy X-ray Silicon Drift Detectors (SDD) for space applications. Fabricated in 180 nm CMOS, it integrates dual-gain charge amplification, shaping, discrimination, peak detection, analog multiplexing, and 12-bit analog-to-digital conversion. The ASIC offers extensive programmability, including high-resolution mode, various discrimination modes, neighbor-channel/chip processing, peak processing modes, and power-down options. At less than 600 µW per channel and ~110 fF input capacitance (SDD anode + wirebond), it achieves an Equivalent Noise Charge (ENC) below 7 e^- (< 6 e^- in high-resolution mode), meeting or exceeding STROBE-X requirements.

NSS-10-02

Towards a 150 kHz Continuous Imager: The CoRDIA 0.5 Prototype 20 k Pixel Array (#2886)

NIKHEF (particularly V. Gromov and A. Vitkovskiy), for allowing the authors to include a version of the PCS-GWT circuit in the CoRDIA design, for fast data readout;
CERN, for allowing the reuse of CMOS IO pads and SOFIC ESD structures in the MPW design;
Europractice, IMEC and CERN for their MPW and design tool support.

Abstract
The Continuous Readout Digitizing Imager Array (CoRDIA) is an X-ray hybrid pixel detector currently being developed for scientific experiments exploiting the performance of 4th generation light sources, in particular that of PETRA IV, but also CW free electron lasers (FELs). Operating on the charge-integrating principle, it adopts the dynamic gain switching architecture and circuit topology of the AGIPD detector at the European XFEL to combine single photon sensitivity with a large dynamic range. Implementing the readout ASIC in a 65 nm CMOS technology enables a small pixel size of 110 × 110 μm^2.
To ensure up to 150 kframes/s dead time free operation, images are stored by a sample and hold (S&H) circuit, before digitisation by an 11 bit SAR ADC serving blocks of 16 pixels each. Data from 128 ADCs (2 kpixels) is driven off-chip by a 5.12 Gbit/s wire transmitter (GWT).
In spring of 2026 we completed the design of the ’20 k’ prototype CoRDIA 0.5, which combines the full signal chain consisting of 1232 4 × 4 pixel blocks (tested on CoRDIA 0.2) with 14 GWTs (tested on Timepix4 and CoRDIA 0.3). This chip also contains a programmable sequencer, controlling the ADC and readout operation. This sequencer is based on an SRAM memory and thus much more flexible than counter-based solutions as implemented e.g. on the AGIPD chip.
In addition to wirebond pads through silicon via (TSV) landing pads are evenly distributed across the whole chip area enabling ’local powering’ for future gapless detectors.
We will present the design of CoRDIA 0.5 with emphasis on the implementation of the readout sequencer, and new characterisation results.

Abstract

In this article we describe the design of the LGAD Integrated Digitizer (LID) - a readout Integrated circuit that is meant for tight coupling with dense LGAD arrays. The circuit is a multi-channel device that performs internal pre-amplification and self-triggered high rate digitization (10 Gsps) and digital processing. The RoIC is an evolution of previous HPSoC chips[1][2][3], and it features variants of the front end Transimpedance amplifier (TIA) that are capable of handling the higher capacitance of strip detectors. The paper will detail the design and performance of the TIAs, the planned integration with sensors, and the definition and hardware implementation of algorithms using waveforms from multiple channels to extract accurate position and timing information. Simulation results in the presence of noise show that the system is capable of fine location to within 10 percent of the sensor pitch and up to 9 ps of timing resolution in the best case.

Abstract

We present the design progress and early test results of SparkPix-S, a charge-integrating readout application specific integrated circuit (ASIC) developed for next-generation X-ray cameras operating at the 1 MHz frame rate of LCLS-II. The SparkPix-S detector is being developed for X-ray Photon Correlation Spectroscopy (XPCS) and Speckle Visibility Spectroscopy (XSVS) experiments, where the inherent sparsity of the data — with average frame occupancies well below 1 % — enables a fundamentally different readout approach compared to conventional full-frame readout ASIC architectures. The pixel front-end architecture combines a charge-integrating front-end, coupled to an in-pixel discriminator to control the sparse readout architecture. 1 MHz operation is achieved through the combination of per-pixel asynchronous sparse readout logic, high-speed CML serial links, and a novel frame-work for sparse readouts named Pix2PGP. The first full-reticle (312 × 384 pixels) prototype has been fabricated in 130 nm CMOS technology. Electrical characterization of the front-end confirms noise performance below 60 electrons r.m.s., enabling single-photon sensitivity for tender X-ray energies. We report on the chip architecture, preliminary measurement results with a silicon sensor bump-bonded to the ASIC, and first results from the sample X-ray source testing with Cd-109 and Am-241, demonstrating the viability of the sparsified readout concept for MHz-rate photon science at free-electron laser facilities.

Abstract

A 10-bit single-slope analog-to-digital converter has been developed in a 110 nm CMOS technology for amplitude measurements in large-area pixel detectors for X-ray imaging. The converter generates the linear ramp and the timestamp in the chip periphery and distributes them to the 256x256 pixels in the chip core for comparison with the local amplitude sample. This approach reduces power dissipation in the chip core and achieves an optimal trade-off between IR-drop effects and front-end noise performance, while preserving the integrity of the analog sample at the pixel level. Although the current detector design targets frame rates in the tens-of-kHz range, the possibility of scaling to higher rates is explored through the implementation of a compression feature that accounts for Poisson noise in the photon signal.

Characterization of the Ignite64 ASIC in CMOS 28-nm technology for high time-resolution tracking (#1913)

Luca Pacher[2], **Adriano Lai**[1], on behalf of IGNITE-Collaboration

[1] Istituto Nazionale Fisica Nucleare, Cagliari, Cagliari, Italy; [2] University of Turin and INFN Torino, Torino, Italy

Abstract

The IGNITE project is developing advanced technical solutions in 28-nm CMOS technology for next-generation collider tracking systems, targeting time resolutions below 40 ps RMS while preserving the key constraints of current inner trackers, namely small pixel dimensions (~50 µm pitch) and low power density (1–2 W/cm.).

This contribution presents characterization results for the Ignite64 prototype ASIC, featuring a 64x64-pixel matrix with 55 µm pitch and one TDC per pixel. The chip has been conceived as a test platform for advanced silicon sensor technologies, including 3D sensors, TI-LGADs, and i-LGADs. The Ignite64 adopts a modular architecture that is directly scalable to the final IgnitER ASIC, currently close to submission.

The prototype implements and validates dedicated solutions for accurate power delivery and low-jitter clock distribution, both essential for achieving uniform timing performance across large pixel matrices. Several alternative Analog Front-End architectures have also been integrated and experimentally evaluated to optimize the trade-off among timing performance, power consumption, and Total Ionizing Dose tolerance.

At an input charge of 1 fC and a power consumption of 10 µW per pixel, the measured timing resolution is approximately 20 ps RMS at zero input capacitance, remaining around 35 ps RMS at a typical pixel capacitance of 100 fF. Performance uniformity across the full matrix is well controlled, with an RMS spread of about 5 ps in the distribution of pixel time resolutions, demonstrating the effectiveness of the adopted architectural and powering strategies.

Comprehensive laboratory characterization results are presented for operation both with and without connected sensors. Measurements include tests performed using the integrated pulsing system, radioactive sources, and a dedicated infrared laser setup capable of accurately reproducing the charge deposition profile generated by charged particles in silicon sensors.

ML-based radiological clearance of activated metallic waste at CERN using synthetic data (#1357)

Andrea Gomes[2,1], Markus Helej[1], Matteo Magistris[1], Francisco Ogallar Ruiz[1], Maria Elisso Stamati[1], Christian Theis[1], Helmut Vincke[1]

[1] CERN, HSE-RP, Geneva, Switzerland; [2] University of Geneva, Physics Department, Geneva, Switzerland

Abstract

The maintenance and dismantling of high-energy accelerators at CERN generate activated waste with significant variability in irradiation history, cooling time, and material composition. If activity levels are negligible, waste can be cleared from regulatory control in Switzerland and reused as conventional material. We present a method for radiological classification which is conservative, without being as penalizing as more traditional approaches based on a worst-case scenario. More specifically, we classify accelerator components as conventional or radioactive based on a radiation measurement (e.g. with a bismuth germanate detector), and on the application of a predictive model. The models here presented were trained over ~60,000 synthetic waste items and their radiological properties. Each synthetic item represents a specific activation scenario, generated through probabilistic sampling of operational parameters. The associated radiological properties were computed with ActiWiz, a CERN-developed activation code based on FLUKA Monte Carlo simulations and evaluated neutron data libraries. Focusing on the classification of metallic accelerator components, we compare the performance of logistic regression based on a bismuth germanate detector response, with that of a neural network model incorporating both the detector response and the item mass. Results show that the neural network improves classification performance and robustness relative to logistic regression, reducing misclassification of borderline cases while maintaining compliance with Swiss regulatory criteria. The proposed framework establishes a robust and scalable clearance workflow, adaptable to the evolving requirements of large-scale research facilities.

Abstract

Radiological characterization is a key step in nuclear decommissioning, particularly during final operations where contaminated concrete structures must be assessed prior to decontamination. Conventional approaches combine surface measurements with radiochemical analyses of samples at different depths, and use geostatistical methods to estimate 3D contamination distributions. Despite their efficacy, these methods remain intrusive, time-consuming, and costly. In this work, we investigate a complementary non-destructive methodology based on in situ gamma spectrometry conducted at the surface using a HPGe detector. The primary objective of this methodology is to reduce the need for destructive sampling and improving the understanding of contamination phenomena in concrete. This study focuses on the analysis of ^{137}Cs, a predominant gamma-emitting radionuclide frequently encountered in nuclear facilities. The proposed approach relies on inverse reconstruction of depth contamination profiles, where the volume of concrete is discretized into layers. The feasibility of the approach was confirmed through simulations. The detector response is modeled using Monte Carlo simulations with MCNP and is combined with the ML-EM algorithm to solve the inverse problem. However, investigations also revealed limitations, especially ambiguities and non-unique solutions in complex configurations. We propose to integrate prior knowledge on the contamination profile (Fickian diffusion) and demonstrate its benefits in addressing the aforementioned limitations. In controlled laboratory conditions, the experimental validation was executed with a calibrated ^{137}Cs point source shielded with a concrete barrier. With this configuration, the ability to estimate source position by using relevant energy ranges were demonstrated. These results highlight both the potential and inherent limitations of ML-EM, thus motivating hybrid approaches combining physics-based modeling and learning methods.

Joint autoencoder-classifier network for particle-type identification in organic scintillator pulse pileup (#1374)

Annamaria R. McHugh, Kurt Beyer, Shaun D. Clarke, Sara A. Pozzi, Majdi I. Radaideh

University of Michigan, Department of Nuclear Engineering and Radiological Sciences, Ann Arbor, USA

This work was supported in part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration, award number DE-NA0003920. The authors would like to thank Dr. Abbas Jinia from the University of Michigan Detection for Nuclear Non-proliferation Group (DNNG) for supplying the waveform dataset used in this study.

Abstract

Charge-comparison pulse-shape discrimination in organic scintillators fails at high irradiation rates due to the effects of pulse pileup. While pileup rejection reduces particle misclassification, this severely degrades detector efficiency. We present a new machine-learning pipeline to extract particle-type information from piled-up trans-stilbene waveforms using a novel joint autoencoder–classifier design. Events are classified as single or pileup, then routed to separate multi-task convolutional autoencoders, which extract the important features of the input waveform and perform n/γ classification. Trained on 519,910 labeled

Time-of-Flight waveforms and synthetically generated pileup data, the system achieves 97.66% accuracy for single/pileup detection, 99.42% n/γ classification accuracy on single pulses, and 90.15% classification accuracy of both constituents in pileup waveforms. This approach is shown to substantially outperform charge-comparison-based analytical pulse-shape discrimination by improving pileup detection and preserving neutron and gamma-ray counts.

NSS-11-04

Joint Neutron Source Localization and Identification using Machine-Learning-based Spectral Imaging (#2042)

David Breitenmoser, Shaun D. Clarke, Sara A. Pozzi

University of Michigan, Department of Nuclear Engineering and Radiological Sciences, Ann Arbor, USA

This work was supported in part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration, award number DE-NA0003920.

Abstract

Neutron source localization and identification are critical for nuclear safeguards and security, yet current scatter-based imaging pipelines typically decouple spatial reconstruction from spectral analysis, treating both as separate post-processing steps. This work introduces a unified machine-learning framework for joint spectral-directional neutron source inference using energy-resolved simple back-projection (SBP) images. The proposed framework combines unsupervised Gaussian mixture model localization with a lightweight k-nearest neighbors classifier. Despite its simplicity, the approach achieves strong performance on controlled laboratory data involving Cf-252 and PuBe sources in single- and mixed-source configurations, with a mean angular localization error <5º and a source classification accuracy >98%. These results demonstrate that low-complexity statistical learning applied to energy-resolved SBP data enables fully automated, end-to-end inference of both source direction and source identity without manual region selection or separate spectral analysis, offering a practical pathway toward more scalable and deployable neutron imaging systems for real-world safeguards and security operations.

Abstract

In this study, a real-time gamma-ray contribution direction imaging system using a Fractal Radiation Imaging Element (FRIE) detector and a Multi-Layer Perceptron (MLP) was developed and evaluated. The system consists of an FRIE detector composed of sixteen GFAG scintillators, a 360-degree camera, and a PC for real-time analysis and visualization. Radiation contribution directions were estimated from count-rate data of the sixteen detectors using an MLP trained with Cs-137 point-source irradiation data including statistical fluctuations. Evaluation results showed that the average angular estimation error was approximately five degrees, and the estimation accuracy improved as the count rate increased. Experiments using measured data demonstrated that the estimated source direction gradually converged through temporal accumulation of measurement data, even under low count-rate conditions. Compared with the conventional similarity-based method, the proposed method reduced the direction estimation error while enabling real-time gamma-ray contribution direction estimation. These results demonstrate the effectiveness of the proposed system for real-time localization of gamma-ray sources in nuclear decommissioning environments.

Evaluating isotope identification methods for use with count-starved gamma spectra (#2536)

James Biggs, Caroline Shenton-Taylor

University of Surrey, School of Mathematics and Physics, Guildford, UK

Abstract

Radiation detector networks provide a potential means of monitoring the movement of radiological material within urban environments. Such systems require automated methods capable of identifying non-background isotopes within collected spectra, particularly for count-starved measurements acquired in complex backgrounds. In 2018, the London-based SIGMA trial collected approximately 1.5 billion one-second gamma spectra using a combination of stationary and mobile scintillation detectors. This work presents a comparison between three viable isotope identification tools, to ascertain which is best placed to be used in environments with count-starved gamma spectra, such as those typically seen in large datasets like SIGMA. Representative spectra were created by combining laboratory collected spectra and Geant4 simulated spectra with real-world SIGMA background. Tranches of spectra were tested in each of the chosen methods: InterSpec, wavelets, and a convolutional neural network. Although all three methods showed promise when identifying a range of ^{137}Cs spectra, the CNN outperformed the others when presented with spectra with the smallest photopeaks, making it the preferred approach for isotope detection in urban landscapes.

Abstract

High-resolution scintillator detectors achieve precise particle tracking through fine segmentation down to a few hundred micrometres, making complexity and costs prohibitive when scaling up to large volumes. We propose a change of paradigm: 3D imaging of particle interactions in an unsegmented monolithic volume of scintillator obtained by combining plenoptic imaging with a Single-Photon Avalanche Diode (SPAD) array sensor. We report the performance of the first SPAD-based plenoptic camera for particle detection, built around the SwissSPAD2 sensor. Results obtained from ^{90}Sr radioactive source, a point light source and a controlled two-photon-absorption setup as well as novel analytical and artificial-intelligence-driven 3D imaging techniques will be described. A simulation case study on neutrino detection demonstrates the unique potential of this approach and its scalability to medium (1 x 1 x 1 m^3) and large (10 x 10 x 10 m^3) scale scintillator volumes, with sub-millimeter 3D spatial resolution. A new custom SPAD array required to enhance the resolution currently under development is also presented. This work sets the path forward for a new system for high-precision particle tracking in dense volumes. Applications of the PLATON concept can also extend to medical imaging.

Abstract

Time-resolved ultrafast phenomena with hard X-rays are central to applications such as pump–probe spectroscopy, driving advances in detector and multichannel acquisition technologies. This work proposes a fully digital 3D (x–y–time) imager for hard X-rays. Key challenges include improving time and spatial resolution—often limited by pixelated approaches—and overcoming the low quantum efficiency of silicon detectors at high photon energies. To address these issues, we adopt a Separate Absorption and Multiplication Avalanche Photodiode (SAM-APD) based on III–V semiconductors. GaAs alloys, with higher atomic number and carrier mobility than silicon, enable significantly improved absorption efficiency and faster response. On the readout side, the shift toward multichannel systems and stringent constraints on power and area per channel motivate a transition from voltage-mode pixel electronics to time-based acquisition, where spatial (x, y) and temporal information are encoded in the detection time. The proposed architecture couples a large-area GaAs SAM-APD (mm-scale diameter) with two Cross Delay Lines (CDLs) and a 4-channel Field-Programmable Gate Array (FPGA)-based Time-to-Digital Converter (TDC) with 15 ps precision. The main challenges are preserving spatial coherence between the interaction point on the detector and the corresponding charge readout location on the CDL, and ensuring capacitive coupling with high signal integrity. Preliminary tests were performed using a 10 × 5 mm² p–i–n diode and laser pulses achieving a spatial precision of <100 µm r.m.s. and a temporal jitter of 68.3 ps r.m.s. Additional measurements show intensity discrimination capability with resolvable signal changes of ~1.2–1.6×. The approach offers a compact and scalable alternative to pixelated detectors, eliminating the need for advanced lithography and per-pixel readout, while relying on only four acquisition channels.

Abstract

The demand for radiation-hard 4D detectors capable of simultaneous high-precision timing and spatial resolution is driving the investigation of 4H-Silicon Carbide (4H-SiC) as a robust alternative to silicon. While 4H-SiC offers superior thermal stability and radiation tolerance, its wide bandgap and current epitaxial thickness limits necessitate the use of internal charge multiplication. This work presents an extensive performance evaluation of 4H-SiC LGADs and PN junction diodes fabricated by Onsemi on 6-inch wafers 50 μm epitaxial layer, n=5 $\cdot 10^{13}$ cm^{-3}. The devices were subjected to 23 MeV proton irradiation, covering five fluences from 1.3 $\cdot 10^{14}$ to 2 $\cdot 10^{15}$ p/cm^2. They have been characterized in terms of current–voltage I-V and capacitance–voltage C-V measurements. The study is complemented by ongoing Transient Current Technique (TCT) and Charge Collection Efficiency (CCE) measurements using a beta source. Furthermore, the impact of temperature (up to 200°C for I-V/C-V and 100°C for beta tests) is investigated to evaluate defect dynamics and the operational stability of 4H-SiC LGADs in extreme environments.

Abstract

The GRAiNITA project aims to develop a novel design for a next-generation calorimeter. It is an innovative approach which uses a mixture of millimeter-sized inorganic scintillating crystals (approximately 1-2 mm) dispersed within a high-density, transparent liquid. Compared to other sampling calorimeter with sensitive material of plastic scintillator, liquid argon, or silicon detector the sampling fluctuation impact on the resolution is predicted by simulation to be much smaller (<2%/sqrt{E}) due to the high density of the scintillator grains compared to the liquid and the smallness of the grains. A test beam operated in June 2024 at CERN allowed to study the performance of a small-scale GRAiNITA prototype. The light light yield was confirmed to be approximately 10 kPE/GeV and we demonstrated the feasibility of achieving sub-2% stochastic and constant terms. Since, the project has advanced significantly. This article presents the latest developments, including the design of a full-scale demonstrator module, advanced Geant4 simulations which are used to evaluate its expected performance, and detailed characterization studies scintillation properties of ZnWO$_4$ using proton beams. These efforts pave the way for the comprehensive validation of a full-scale detector.

Small Dose Monitor based on Silicon Carbide diodes for FLASH radiotherapy (#2594)

Celeste Fleta[1], Iván López[1], Ángela Henao[1], Sophie Heinrich[2], **Consuelo Guardiola**[1]

[1] National Center of Microelectronics (IMB-CNM, CSIC), Barcelona, Spain; [2] University Paris-Saclay, Orsay, France, Institut Curie, Inserm U1021-CNRS UMR 3347, Orsay, France

The project has received support from the Spanish government through the ‘María de Maeztu Unit of Excellence’ accreditation (CEX2023-001397-M / AEI/10.13039/501100011033).

Abstract

FLASH radiotherapy (FLASH RT), delivered at ultra-high dose rates (>40 Gy/s), has shown potential to reduce toxicity in healthy tissues while preserving tumor control. However, accurate, real-time dosimetry at such conditions remains challenging due to limitations of conventional detectors, including saturation effects and insufficient temporal resolution. In this work, silicon carbide (SiC) diodes are investigated as a promising solution for ultra-high dose rate (UHDR) dosimetry due to their high radiation hardness, fast response, and low sensitivity to saturation [1].

A 4 × 4 array of SiC diodes (1 mm diameter, 2.2 mm pitch) and a single 2.2 mm diode were tested using pulsed 7 MeV electron beams under FLASH conditions. The detectors were evaluated in terms of linearity, time response, and spatial dose measurement capabilities using a clinical reference dosimeter and radiochromic films for comparison. The single diode demonstrated excellent linearity better than 3.5% up to 10 Gy per pulse, with no evidence of saturation or radiation damage. Time-resolved measurements confirmed the capability to resolve sub-microsecond pulse structures, consistent with accelerator signals.

The SiC array prototype enabled spatially resolved dose measurements over areas up to 70 × 50 mm², producing 2D dose maps with millimeter-scale resolution under UHDR conditions. Good agreement with independent film measurements demonstrates its accuracy for beam profiling. These results highlight the feasibility of SiC-based detectors as scalable, position-sensitive dose monitors for FLASH RT [2].

Overall, this work demonstrates the potential of SiC technology for real-time, high-resolution dosimetry in FLASH radiotherapy, paving the way for future large-area detector systems and improved quality assurance in UHDR treatments.

Abstract

Ultra-high dose rate (UHDR) radiotherapy, commonly known as FLASH radio-therapy, is a revolutionary oncological approach that spares healthy tissue while preserving tumor control. Clinical translation of this method needs radiation detectors that provide real-time dosimetry under extreme dose rates, exceeding 40-100 Gy/s. Standard dosimeters, such as ionization chambers and traditional semiconductors, may face limitations like charge recombination and signal saturation in these environments. This study investigates full-inorganic metal-halide perovskites ($CsPbBr_3$) as viable detector material due to its high stopping power and moderately wide bandgap. We evaluated two distinct device architectures: thin-film (TF) and single-crystal (SC) detectors. The 1 µm-thick TF detectors were fabricated using radio-frequency magnetron sputtering (MS) on flexible Kapton substrates with interdigitated electrodes. SC detectors featured Schottky-Ohmic electrodes (Ti/Au and Au) deposited by DC-MS on pure commercial crystals. Characterization indicated a dominant CsPbBr3 phase, a forbidden gap of 2.32 eV, and a dark resistivity of approximately 10^7 Ωcm. Experimental validation was performed using a 9 MeV electron beam at Centro Pisano FLASH Radiotherapy (CPFR) and a 228 MeV proton beam at APSS (Azienda Provinciali Servizi Sanitari) Trento proton-therapy center. The tests with 9MeV electron beams covered a dose-per-pulse (DPP) range of 0.1 to 5.0 Gy delivered in 4us-long pulses, while proton testing reached dose-rates of 300 Gy/s with pulse durations of 10-25ms. Both detector types demonstrated good signal linearity and showed no evidence of saturation at the highest tested intensities. Ultimately, these results confirm that CsPbBr3 perovskite detectors are suitable for real-time monitoring in both electron and proton FLASH radiotherapy.

Abstract

At CNAO, carbon-ion beams are delivered by the standard scheme which uses betatron-core extraction of a debunched beam, while RF Knock-Out (RFKO) extraction keeps the beam bunched and drives particles transversely toward extraction. To resolve the fine temporal structure of these modes beyond the 100 ms limit of standard ESA-ABACUS readout, a High-Rate DAQ system with 10 ns time bins was developed. The system used the LVDS outputs of 48 central channels from two ABACUS ASICs connected to a Xilinx Kintex-7 FPGA implementing custom VHDL firmware. Counts were aggregated in 10 ns windows, stored in DDR3 memory, and analyzed offline to reconstruct beam-rate waveforms and frequency components.

Tests were performed at CNAO with clinical carbon-ion beams using Betatron and RFKO extraction at four energies (115, 209, 304, and 398 MeV/u) and three intensity levels (20%, 50%, 100%).

A CAEN DT5203 picoTDC was also used as an independent acquisition system to record leading- and trailing-edge timing information from 32 ESA-ABACUS outputs in Streaming mode. The High-Rate DAQ resolved clear differences between the two extraction modes: RFKO showed a more compact and regular bunched time structure, while Betatron extraction showed the broader temporal distribution expected from a debunched coasting beam.

Fast Fourier Transform analysis of the High-Rate DAQ waveforms allowed the main accelerator RF components to be estimated with deviations below 0.25% for all tested conditions.

The DT5203 provided complementary hit-by-hit timing and enabled bunch-spacing estimation with <1.5% deviations, but suffered rate saturation at high intensities.

Overall, the High-Rate DAQ proved suitable for fine beam-structure measurements under clinical carbon-ion conditions, supporting accelerator tuning, particularly for RFKO operation.

Abstract

This work investigates diamond nitrogen-vacancy (NV) centers as a new class of neutron dosimetry that uses neutron-induced defect formation as the sensing mechanism rather than treating radiation damage as a failure mode. There is no device fabrication, wire connection, or charge collection as the diamond works purely as a passive dosimeter. Fast neutrons generate carbon vacancies in nitrogen-enriched diamond, followed by high-temperature annealing to form stable NV centers exhibiting characteristic photoluminescence and optically detected magnetic resonance responses. Eight nitrogen-rich diamond samples were irradiated at The Ohio State University Research Reactor, with fluence ranging from 10^{15} n/cm^2 to 10^{17} n/cm^2, and then annealed at 800 °C for a few hours. The results demonstrated a strong linear correlation between fluorescence intensity and neutron fluence, with up to 403× fluorescence increase observed after annealing compared to control samples. The results support the feasibility of applying diamond as compact, passive, and radiation-hardened sensors for high-fluence neutron detection in nuclear fission and fusion systems. The ongoing work is also exploring the real-time sensing using a diamond quantum sensor.

Abstract

Ensuring reliable RF operation in radiation-prone is critical for wireless monitoring systems in nuclear and space applications. This work presents a radiation-hardened-by-design (RHBD) voltage-controlled oscillator (VCO) implemented in a 28 nm Fully-Depleted Silicon-On-Insulator (FDSOI) process and experimentally evaluated under total ionizing dose (TID) conditions. The proposed RHBD VCO is compared with a conventional design up to 370 kGy(Si) using a Cobalt-60 gamma irradiation source at KAERI. Measurement results demonstrate that the RHBD VCO significantly improves frequency stability, achieving up to 57% reduction in frequency drift compared to the conventional counterpart. In addition, enhanced output power stability and reduced supply current variation are observed under irradiation. The results highlight the combined benefits of FDSOI technology and circuit-level hardening techniques, demonstrating a robust solution for radiation-tolerant RF circuit design.

Abstract

The next generation of imaging atmospheric Cherenkov telescope (IACT) cameras is transitioning to silicon photomultipliers (SiPMs) due to their stability, robustness, and superior sensitivity compared to PMTs. Specifically, we are developing an ASIC for the advanced SiPM camera (AdvCam). This ASIC, designated as PRESSEC (Preamplifier Readout Electronics for Summing SiPMs Enhanced Circuit), is implemented in 65 nm CMOS technology. The PRESSEC utilizes a 32-input scheme for large-area sensor readout. Its primary function is to generate analog outputs by summing signals from four sensors into a single channel, effectively reducing the total output count to eight channels. The main functionality of this ASIC is housed in the energy path, which integrates a single-ended-to-differential converter and a pole-zero cancellation circuit. This structure is instrumental in reducing the pulse’s Full Width at Half Maximum (FWHM) to 3 to 5 ns, thereby mitigating pileup effects in high activity environments. Simultaneously, these signals feed a trigger system for rapid event identification via a fast comparator. Additionally, a dedicated Night-Sky Background (NSB) monitoring circuit is included to measure ambient noise from sources like moonlight, employing a slow integrator with adjustable high-value pseudo-resistors to achieve integration time constants in the order of the milliseconds. Rigorous performance benchmarks, validated using Hamamatsu and FBK SiPMs, show a signal-to-noise ratio of at least 5, a dynamic range of 300 photons, and a linearity error below 3% for both energy and NSB paths, while presenting a power consumption of approximately 10 mW per input channel.

Abstract

The experimental characterization of MAGIC (Multichannel Analog Gamma- ray detection Integrated Circuit) is here presented. This ASIC is designed in CMOS 110 nm technology and it is intended to readout the current signals coming from SiPMs coupled with monolithic scintillators that are used in medical imaging applications. The circuit is divided into three main sections: an energy path that provides a differential voltage proportional to the energy of the gamma photon, a timing path that gives information about the time of arrival of the photon, and a validation path for event discrimination. For the experimental characterization two PCBs, a mainboard and a carrier, have been designed. In this testing phase all the functionalities have been validated and the key performance of the ASIC have been characterized, in particular the power dissipation (5 mW/channel), the linearity of the energy chain to demonstrate the direct proportionality between the measured charge and the one generated by photon interaction, and the time jitter which affects the propagation delay through the timing path. The results are within the specifications and confirmed by simulations: the linearity error is below 1% and the time jitter is below 20 ps. Such a low value enables its use also in TOF-PET applications.

Photon Counting with FPGA Gigabit Transceivers: A Proof-of-Concept SiPM Readout for TOF-PET (#2884)

Tarun Prakash, Joshua W. Cates, Woon-Seng Choong, Marcos Turqueti

Lawrence Berkeley National Laboratory, Berkeley, USA

This work was supported in part by NIH Research under Grant R01EB033402

Abstract

Achieving 100ps FWHM coincidence time resolution (CTR) in time-of-flight positron emission tomography (TOF-PET) is benefited by electronics that can resolve individual scintillation photons with high temporal precision. We report a proof-of-concept readout in which silicon photomultiplier (SiPM) single-photon pulses are discriminated by a high-speed comparator and digitized directly by GTY transceivers of a Xilinx Virtex UltraScale XCVU095 FPGA (VCU1287 board) at 16Gbps, encoding photon arrival times as bit positions with 62.5ps resolution. Signal integrity analysis showed that an initial LVDS comparator produced common-mode voltage and differential swing below GTY receiver specifications; switching to a CML comparator substantially reduced bit errors. Room-temperature SiPM dark count bitstreams were captured with a random FPGA clock trigger and post-processed to produce a finger plot showing 1-, 2-, and 3-photoelectron peaks, providing a preliminary validation of the bitstream-based photon-counting concept. These results support the feasibility of FPGA gigabit transceivers as scalable digitizers for single-photon pulse streams in next-generation TOF-PET detector modules.

Abstract

Traditional radioactive source testing involves health risks, regulatory limitations, and operational inconvenience. To address these issues, this paper presents a nuclear-like signal generator capable of reproducing the waveform, amplitude, and timing characteristics of real nuclear radiation signals. The proposed system is implemented on a Xilinx K7 FPGA and supports parameter configuration through a touch screen, USB, Ethernet, or host computer software. In the waveform-generation module, photon emission timing is modeled according to scintillator light yield and decay time, while photoelectric conversion jitter and Gaussian pulse responses are introduced to synthesize realistic macroscopic waveforms. In the amplitude-generation module, a cumulative distribution function threshold table derived from measured energy spectra is used to reproduce statistical energy distributions. In the timing module, event occurrence is modeled as a Poisson process with exponentially distributed intervals. The system supports multiple radioactive sources and scintillator materials, including Na, Cs, LYSO, NaI, CsI, and BGO, with independent dual-channel output capability.

High-performance preamplifier for spectroscopy systems based on High-Purity Germanium detectors (#1999)

Fernando Ojeda, Fernando Ojeda, Brian Nelson, Brian Nelson

AMETEK ORTEC, Oak Ridge, USA

The authors wish to acknowledge the valuable contributions to this work from the Engineering, Production, and Detector Test teams.

Abstract
Preamplifiers play a primary role in the resolution, linearity, and sensitivity of ionizing radiation spectrometers, converting the small charges collected by photo detectors into usable voltage signals that are further amplified, digitized, and processed to obtain the intended spectra. Additionally, the accuracy and thermal stability of such charge-to-voltage conversion must be assured to keep a constant performance over time and across different detectors, wiring configurations, and radiation scenarios. This article presents electronic simulations and the first laboratory results showing recent improvements in a new preamplifier designed for High-Purity Germanium spectroscopy systems, in terms of dynamic response, noise, linearity, thermal stability, symmetry, tolerance to reactive loads, piling-up, saturation recovery, and power consumption. The impact of these improvements is also discussed.

Preliminary Test Results on Latest Version of FESA Readout ASIC for TOF-PET Detectors (#2565)

Yuhao Yang, Yonggang Wang, Xinchi Xu, Xiang Zhang, Huandong Huang

University of Science and Technology of China, Department of Modern Physics, Hefei, China

Abstract
The latest version of the low-power 64-channel Front-End readout chip for SiPM Array (FESA4.0) with the preliminary test results is presented in this paper. Using a row-column summing readout method, FESA compresses the 64 input signals into 16 output digital pulses, which then is digitized by the followed field programmable gate array (FPGA). In the pathway of each summing output, there are two threshold current comparators used for signal pickup, one with a low threshold for signal timing and the other with a high threshold for signal validation. Since the signal amplitude is converted into the pulse time-width via the linear discharge method, both the signals timing and amplitude can be measured by the time-to-digital converter (TDC) in the FPGA. The new version of FESA incorporates a time-over-threshold (TOT) measurement capability, which allows to identify the signals originating from different scintillators. The chip offers prominent advantages of simple architecture, low power consumption, and high performance. Through electronics tests, FESA4.0 has a measurement linearity of 99. 1% with a dynamic range of 140. The intrinsic time measurement precision is measured better than 30 ps. Combined with a TOF-PET detector with an 8×8 LYSO crystal coupled to an 8x8 SiPM, the energy resolution and time coincidence resolution are measured as 279 ps and 12.4% respectively.

These test results show that FESA4.0 is very promising for the construction of highly integrated TOF-PET scanners.

Single-Shot Precision Decomposition of a 64-Channel FPGA TDC for TOF-PET (#2381)

Giancarlo Sportelli[1,2], Matteo Morrocchi[1,2], Nicola Belcari[1,2]

[1] University of Pisa, Department of Physics "E. Fermi", Pisa, Italy; [2] INFN, Sezione di Pisa, Pisa, Italy

The authors would like to thank TEDIEL s.r.l. for the technical support on FPGA TDC architecture implementation and validation.

Abstract

We report a channel-level characterization of a calibrated 64-channel FPGA Time-to-Digital Converter (TDC) for fast-timing TOF-PET, with explicit decomposition of the single-shot precision (SSP) into quantization and jitter contributions. The TDC is implemented on an Altera Cyclone 10 GX device and operates with a 256-tap, 64-bin tapped-delay-line (TDL) at ~400 MHz, calibrated offline via code-density histograms. Two implementation strategies are compared: the default arithmetic carry-chain inference, and a placement-aware variant in which the TDLs are constrained to regular structures. Across all 64 channels, controlled placement reduces the ultra-bin width from 160 ± 76 ps to 101 ± 12 ps, the equivalent LSB (LSBeq) from 83 ± 32 ps to 63 ± 4 ps, and the quantization noise σ_Q from 24.5 ± 7.3 ps rms to 18.1 ± 0.8 ps rms. The placement-constrained implementation also substantially improves channel-to-channel uniformity. The constrained routing increases σ_{jitter} which makes jitter the dominant SSP contribution once σ_Q is reduced. A system-level projection onto previously characterized UTOFPET monolithic modules indicates that the TDC accounts for 59% of the measured CRT² in a 12 mm LYSO/256-channel module (CRT ≈ 150 ps FWHM), but only ~8% in 16–20 mm BGO/64-channel modules (CRT ≈ 400 ps FWHM). This identifies σ_{jitter} as the dominant architectural ceiling and motivates wave-union/multi-TDC averaging or finer-node FPGAs for full LYSO exploitation.

SEU Evaluation of an Atom Switch-based FPGA for Slow-Control Systems (#2501)

Kazuki Ueno[1], Nanae Taniguchi[2], Toshitsugu Sakamoto[3], Makoto Miyamura[3]

[1] The University of Osaka, Department of Physics, Osaka, Japan; [2] KEK, Institute of Particle and Nuclear Studies, Tsukuba, Japan; [3] NanoBridge Semiconductor, Inc., Tsukuba, Japan

Abstract

Atom Switch-based FPGAs (AS-FPGAs) are being developed as next-generation FPGAs with expected high radiation tolerance. Their application to various radiation environments is anticipated, and we are also investigating their potential use in detector electronics for future high-energy physics experiments. In this study, neutron irradiation tests were performed to evaluate the Single Event Upset (SEU) tolerance of digital resources implemented in a 65 nm AS-FPGA. A prototype slow-control board equipped with the AS-FPGA was developed and used for the irradiation test. Two independent block RAM (BRAM) blocks and D-type flip-flop (DFF) blocks were implemented in the FPGA for SEU evaluation, and data mismatches detected during irradiation were counted as SEU events. Neutron irradiation tests were carried out using the tandem accelerator at Kobe University. The neutron fluence reached 1.2×10^{11} n/cm^2. No SEUs were observed in the DFF blocks, while approximately 10 SEUs were detected in the BRAM blocks. The preliminary SEU cross section for the BRAMs was estimated to be on the order of 10^{-9} cm^2/Mbit. In parallel with the irradiation studies, stable acquisition of temperature and pressure data from a commercial environmental sensor connected to the prototype slow-control board was successfully demonstrated during neutron irradiation, indicating the applicability of the AS-FPGA to detector slow-control systems in radiation environments.

Abstract

Correlating molecular neuroimaging with behavior in preclinical models requires acquisitions in awake and freely moving animals, whereas most current positron emission tomography procedures are still performed under anesthesia.
The MAPSSIC project addresses this limitation with an implantable intracerebral probe based on monolithic active pixel sensors (MAPS) for direct positron detection in targeted brain structures of awake, freely moving rats, thereby avoiding the pharmacological bias of anesthesia. Following sensor characterization and simulation studies previously reported, this contribution presents the transition to a fully wireless system. The acquisition chain combines four IMIC2 sensor chips, a STM32L4 microcontroller, 1 Gbit on-board flash memory, and a bidirectional 2.4 GHz radio link to a Raspberry Pi ground station. The complete software stack is implemented in Rust with the Embassy asynchronous framework, providing memory safety and concurrent peripheral management without dynamic allocation. Planned validation with ^{18}F, ^{11}C phantoms, and anesthetized implanted rats will mark the shift from sensor feasibility to system-level wireless validation.

Abstract
The COMET (COherent Muon to Electron Transition) Phase-I experiment at J-PARC searches for coherent muon-to-electron conversion in aluminum with a single-event sensitivity of 3 x 10^-15. A key detector challenge is the high instantaneous beam rate, which produces background hits in the Cylindrical Drift Chamber (CDC). In particular, low-energy protons can generate large ionization signals that drive the readout electronics into nonlinear regions, producing waveform saturation and pileups. These effects may reduce hit efficiency by masking later signal or background hits and therefore must be modeled realistically in performance studies. We developed a detector response model for the CDC that combines Geant4-based ionization with the Photon Absorption Ionization (PAI) model, Garfield++-based drift time calculation, and an electronics response emulation based on measured response functions. The model explicitly includes nonlinear saturation effects in the circuit and was validated using cosmic-ray test data. The measured-response model reproduces the main features of the data more accurately than a simple linear-response model. The remaining discrepancy corresponds to a limited uncertainty in the pileup-effect evaluation, providing a realistic basis for COMET Phase-I reconstruction and performance studies.

Abstract

This work reports on the experimental characterization, modeling and correction of high intensity effects on the pixel response of the DEPFET Sensor with Signal Compression (DSSC) camera, an active pixel detector targeted at soft X-ray imaging experiments at the European XFEL. Experimental tests with up to 5 MeV/pixel deposited energy have been performed at the European XFEL, showing evidence of a shift of the pedestal value growing with X-ray intensity. Moreover, the signal compression provided by the DEPFET (DEpleted P-type Field Effect Transistor), integrated in each pixel, enhances the impact of this systematic effect on the measurement accuracy. The observed shift is assumed to be proportional to the signal dependent drop of the power supply lines along each ASIC column and can be modeled by two parameters. We devised a procedure to efficiently measure the two model parameters by means of a custom mask that shields a fraction of each ASIC column, irradiated with a flat field. The main results of the characterization of the signal dependent pedestal shift parameters and the application of the resulting correction to X-ray images of different patterned masks (dots, stripes, 2D shapes etc.) acquired at increasing intensities will be presented and discussed.

Towards a 64-Channel Monolithic SDD X-Ray Spectrometer for High-Throughput Synchrotron Applications (#2776)

Beatrice Pedretti[1,2], Pietro Barcella[1,2], Andrea Abba[3], Giacomo Borghi[1,2], Marco Carminati[1,2], Carlo E. Fiorini[1,2]

[1] Politecnico di Milano, DEIB, Milano, Italy; [2] INFN, Milano, Milano, Italy; [3] Nuclear Instruments srl, Lambrugo, Italy

Abstract

The increasing brilliance of fourth-generation synchrotron sources drives a growing demand for energy-dispersive X-ray fluorescence (XRF) spectrometers capable of handling extreme photon fluxes.

We present the design and characterization of the ARDESIA-64 instrument, a complete X-ray fluorescence (XRF) spectrometer for high-throughput synchrotron applications.

The instrument integrates a highly scaled 64-channel monolithic Silicon Drift Detector (SDD) array, featuring a pixel pitch of 2.5 mm, within a compact, vacuum-compatible mechanical housing tailored for beamline integration.

At the conference, we will present the instrument design and comprehensive spectroscopic characterization results.

The collimated 450 µm-thick sensor variant demonstrates an excellent average energy resolution of 125.9 eV FWHM at 5.9 keV. Preliminary high-rate tests confirm exceptional throughput capabilities, sustaining Input Count Rates (ICR) exceeding 800 kcps per channel while preserving an energy resolution of ~150 eV. The readout is performed by a 64-channel Digital Pulse Processor (DPP) based on the CAEN DT5560SE digitizer with firmware specifically adapted for high-throughput X-ray spectroscopy in synchrotrons.

Education kit for radiation measurements (#2477)

Masaharu Nomachi

The University of Osaka, RCNP, Ibaraki/Osaka, Japan

This work is supported by IEEE/NPSS Initiative.

Abstract

We have been organizing schools on radiation measurements for students from ASEAN countries. Hands-on experience with radiation measurements is very important, and we prepare radiation measurement systems for practical exercises.

To host as many students as possible, we considered organizing the schools in ASEAN countries. However, the shipping cost of the equipment was extremely high. As a result, we could not conduct hands-on exercises on radiation measurement.

Driven by recent large-scale experiments, electronics for radiation measurements have become compact, highly integrated, and low-cost. This development now makes it possible to carry equipment to schools.

Today, compact detector systems are available at affordable prices, making it much easier to conduct practical radiation measurement exercises in schools.

However, modern compact electronics have introduced a new problem: they are too small to probe easily with an oscilloscope. In modern electronics, waveform processing is increasingly performed digitally. Nevertheless, we believe that analogue processing remains important and highly educational for students. This motivated us to develop electronics specifically for educational purposes.

We have developed an “education kit” for radiation measurement education. By plugging in a SiPM and a small scintillator crystal module, the board functions as a complete radiation measurement system. An on-board FPGA interfaces with a PC through a USB connection. The board is the size of a Raspberry Pi board. Optionally, it can be plugged onto a Raspberry Pi.

Although the board is compact, it provides sufficient space for probing signals. The design of the board will be released as open-source hardware. Students can modify the design and develop their own versions of the board. The “education kit” will serve as an entry point to radiation measurement electronics.

Recoil electron tracking in 3D CZT drift strip detectors: a feasibility study (#2296)

Michał Kossakowski[1], Alejandro Valverde Mahou[2], Søren Hauberg[2], Irfan Kuvvetli[1]

[1] Technical University of Denmark, Space Research and Technology, Lyngby, Denmark; [2] Technical University of Denmark, Applied Mathematics and Computer Science, Lyngby, Denmark

This work was supported by the Danish Data Science Academy, funded by the Novo Nordisk Foundation (NNF21SA0069429) and the VILLUM FONDEN (40516). The first author also acknowledges the i-RASE (Intelligent Radiation Sensor Readout System) project team for their support and collaboration.

Abstract

Bridging the *MeV gap* remains difficult due to the interplay of competing photon interaction processes, leaving a persistent sensitivity gap in gamma-ray astronomy. Compton telescopes based on 3D CZT Drift Strip Detectors (DSD) are promising candidates for bridging this gap, offering room-temperature operation, high stopping power, excellent energy and position resolution. A key open question is whether recoil electron tracking, which significantly improves angular resolution and detector sensitivity is achievable from raw detector signals. We investigate this using a machine learning approach trained on forward simulations of the 3D CZT DSD response. Principal Component Analysis of simulated electron tracks confirms that track structure is encodable in a low-dimensional representation, and neural network training to regress the recoil direction directly from detector waveforms is ongoing.

CVAE-Based Synthetic Thermoluminescence Silica Glass Jewellery Bead Glow Curve Generation (#2606)

Lukasz Tomaszewski, Caroline Shenton-Taylor

University of Surrey, Department of Physics, Guildford, UK

This work was funded and supported by the Nuclear Threat Reduction Network (NTR-Net), UK Ministry of Defence
© Crown Owned Copyright 2026/AWE.

Abstract
Micro silica glass jewellery beads have emerged as a viable material for thermoluminescence dosimetry (TLD), offering a low-cost and widely accessible option for personal dose assessment. Their linear glow curve responses, governed by irradiation, thermal conditions, and sample characteristics, exhibit unique spectral elements and structure variability. While machine learning (ML) methods have been successfully applied to dose estimation and irradiation analysis, can ML be used to elevate silica glass beads beyond just decorative jewellery? In this work, a Conditional Variational Autoencoder (CVAE) is implemented to model and generate thermoluminescent glow curves from silica glass beads conditioned on experimental parameters. The model is trained on a dataset of experimentally acquired responses, augmented with Poisson noise to increase the dataset size and robustness. Conditioning variables include temperature profiles, irradiation and sample characteristics, enabling the model to learn relationships between physical conditions and the glow curve. Results show that the CVAE model can generate realistic glow curves that reflect the underlying conditioning variables. Generated predications maintain peak structure and overall shape, while also reproducing the expected linear relationship between total counts and absorbed dose. Model performance remains consistent when evaluated on previously unseen testing data with a mean figure of merit of 7.5%, although accuracy declines at low dose levels due to diminished signal intensity. The proposed approach demonstrates the potential of generative ML techniques for supporting dosimetry simulation, calibration, and data augmentation workflows for future research.

Characterizing Neutron Detection Efficiency in Timepix3: A Bayesian-Optimized FLUKA Approach (#3239)

Angel Mercado, Sharmistha Mukhopadhyay, Malachi West, Patrick Connolly, Shaheen Dewji

Georgia Institute of Technology, Atlanta, USA

Abstract
Characterization of converter layer geometry is critical for determining the absolute detection efficiency of pixelated thermal neutron detectors. However, uncertainties in film deposition and source strength often lead to significant discrepancies between simulated models and actual experimental performance. This work addresses these challenges by implementing a Bayesian optimized FLUKA framework to determine the effective enriched Lithium-6 Fluoride converter thickness for an ADVACAM Timepix3 detector with a 1000 µm Silicon sensor. The FLUKA Monte Carlo model was benchmarked against experimental measurements using an Americium-Beryllium source with a nominal activity of 40 mCi and a documented tolerance of fifteen percent. The Bayesian optimizer successfully converged to an effective thickness of 5 µm after forty evaluations by minimizing the residuals between the nominal source activity and the simulation-implied activities. This methodology demonstrates a robust approach to resolving geometric uncertainties in hybrid semiconductor detectors where direct physical measurement of internal components is not feasible post-assembly. The resulting validated geometry provides a

high-fidelity foundation for modeling future detection efficiency benchmarks across diverse neutron spectra. This work demonstrates a practical approach for integrating machine-learning optimization with Monte Carlo transport modeling to address geometric uncertainties in neutron detectors.

Enhanced Spent Nuclear Fuel Characterization Using Sequential Detector Responses through Deep Learning (#2393)

Beomkyu Kwon[1], Wooseong Hong[1,2], Jaehyo Kim[1,2], Geehyun Kim[1,2]

[1] Seoul National University, Nuclear Engineering, seoul, South Korea; [2] Seoul National University, Energy Systems Engineering, seoul, South Korea

This work was supported by the Nuclear Safety Research Program through the Korea Foundation of Nuclear Safety (KoFONS) using the financial resource granted by the Nuclear Safety and Security Commission (NSSC) of the Republic of Korea. (RS-2022-KN073410)

Abstract

Accurate characterization of spent nuclear fuel (SNF) is essential for verifying operator-declared information in nuclear safeguards. Conventional nondestructive assay (NDA) approaches for such characterization based on gamma-ray spectroscopy typically rely on extracting specific photopeak information (ex. 662 keV peak of ^{137}Cs), which compresses high-dimensional detector responses into a limited number of variables and may lead to information loss. To address this limitation, we propose a deep learning–based SNF characterization approach that directly utilizes sequential detector-response data for advanced characterization performance. The training dataset was generated through integrated ORIGEN and MCNP simulations for 5000 realistic SNF conditions, covering variations in initial enrichment, burnup, and cooling time. The proposed C2C-GRU-v2 architecture was designed to process long sequential detector-response data by combining Coordinate-to-Context embedding and GRU-based recurrent sequence modeling, enabling both event-level contextual learning and sequence-level generalization. For comparison, a conventional spectrum-based regression method using ^{137}Cs peak counts was also implemented under identical conditions. The proposed approach demonstrated improved characterization performance compared with the conventional method, particularly for cooling time estimation, achieving Relative Root Mean Square Errors (RRMSE) of 0.157 for burnup and 0.0456 for cooling time prediction. These results demonstrate the feasibility of deep learning–based sequential detector-response analysis for advanced SNF characterization in nuclear safeguards applications.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (Ministry of Science and ICT) (No. RS-2022-00165164).

Abstract

Gamma-ray spectroscopy is a fundamental technique for radioisotope identification and quantification across safety-critical applications, where deep learning models have recently emerged as a data-driven alternative to traditional library-dependent methods. However, most existing deep learning approaches operate under a closed-set assumption that all isotopes during deployment are present in the training set; field deployments frequently violate this assumption, and the introduction of unknown isotopes leads to silent degradation. Recent OOD-detection studies have been reported, but they treat OOD spectra as anomalies to be flagged rather than quantified, and systematic evaluation under increasing unseen contaminant complexity remains lacking. This study proposes a denoising autoencoder (DAE) framework that reconstructs the clean target spectrum (^{137}Cs, ^{133}Ba) from contaminated measurements while simultaneously estimating target fractions through a dual-head architecture. Using Ce:GPS scintillator pulse data under a leave-one-out unknown noise (LOO-UN) protocol, the DAE achieved a mean absolute error (MAE) of 0.024 at 20% out-of-distribution (OOD) contamination in the two-unseen configuration, outperforming NNLS-known (0.038) and MLP (0.031), with near-constant accuracy as the unseen contaminant count increased from one to two (0.025 → 0.024).

Automated Monte Carlo-Based Efficiency Transfer Integrated into HPGe Gamma Spectroscopy Workflows for High-Throughput Laboratories (#1579)

Spencer Behling[1], Felix Diel[3], Marc Breidenbach[2]

[1] Ametek, Ortec, Oak Ridge, USA; [2] AMETEK GmbH, Meerbusch, Duesseldorf, Germany; [3] AMETEK GmbH, InnoRIID, Duesseldorf, Germany

Abstract

High-purity germanium (HPGe) detector systems are widely used for gamma spectroscopy; however, increasing throughput demands, expanding measurement configurations, and a declining base of expert users have made traditional efficiency calibration and transfer workflows increasingly impractical. Efficiency transfer between counting geometries has historically required manual configuration, custom made sources, and/or execution of Monte Carlo simulations by trained computational physicists, limiting scalability in routine laboratory environments. We present an approach that embeds Monte Carlo-based efficiency transfer directly within a commercial spectral analysis software stack, enabling automated operation without additional user intervention. At runtime, sample geometries—already specified by laboratory personnel using standard container templates such as Marinelli beakers—are used to drive a ray-tracing-based gamma transport simulation coupled to detector interaction and pulse-processing models. The approach operates over an energy range of 20 keV to 2.5 MeV and produces both full spectra and efficiency curves.

Validation is performed through comparison of simulated spectra and efficiency curves against measured data and results from the Geant4 Monte Carlo toolkit. While not intended to match the full generality of Geant4, the proposed approach demonstrates comparable practical accuracy for routine laboratory configurations while significantly reducing user complexity. Additionally, seamless integration into existing workflows is demonstrated, enabling non-expert users to apply physics-based efficiency transfer without specialized training.

This work provides a scalable solution for automated, high-throughput gamma spectroscopy, bridging the gap between rigorous Monte Carlo modeling and practical laboratory usability.

Neutron and secondary photon dose mapping of deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators via PHITS simulations (#2970)

Andrea G. Alipio[1], Christine L. Dulohan[1], Bernhard Egwolf[2], Alvie Asuncion-Astronomo[3]

[1] University of Santo Tomas, The Graduate School, Manila, Philippines; [2] University of Santo Tomas, Department of Mathematics and Physics, Manila, Philippines; [3] Department of Science and Technology, Philippine Nuclear Research Institute, Quezon City, Philippines

This work is supported by the DOST-PCIEERD-funded project NURAD Component 2: "Accelerator Driven Subcritical Nuclear Reactor" with Project Number 1211979.

Abstract

The Monte Carlo-based Particle Heavy Ion Transport Code System (PHITS) was used to model deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators for preliminary radiation safety assessment of the ongoing establishment of the Neutron Irradiation Facility (NIF) of the Philippine Nuclear Research Institute (PNRI). Neutron and secondary photon dose distributions were obtained for fully shielded, partially shielded, and unshielded configurations. In both D-D and D-T cases, the counting room dose rates were acceptable with respect to occupational dose limits for a 500-hour annual operating time. However, additional shielding should be explored for the D-T setup to further reduce dose rates in the work area. The dose maps presented the significance of the configuration of moderating and shielding materials in minimizing radiological doses during operation. The findings of this work will serve as a reference for the safe and reliable installation of the country's first neutron generator laboratory.

Bayesian Filtering Image Reconstruction for SourceLocalization and Tracking in Compton Imaging (#2167)

John Leland[1], Cecilia Tarpau[2], Ming Fang[1], Yoann Altmann[3], Angela Di Fulvio[1]

[1] University of Illinois Urbana-Champaign, Nuclear, Plasma, and Radiological Engineering, Urbana, USA; [2] University of Edinburgh, Maxwell Institute for Mathematical Sciences, Bayes Center, Edinburgh, UK; [3] Heriot-Watt University, School of Engineering and Physical Sciences, Edinburgh, UK

This material is based upon work supported in part by the Department of Energy National Nuclear Security Administration through the Nuclear Science and Security Consortium under Award Number DE-NA0003996.

Abstract

Stand-off detection of special nuclear materials (SNM) in safeguards and non-proliferation applications demands imaging systems capable of tracking sources across dynamic environments. In this work, we introduce a Bayesian-Filtering (BF) algorithm for simultaneous source localization and tracking where existing reconstruction methods, such as simple back-projection (SBP) and maximum likelihood expectation maximization (MLEM), are insufficient. We evaluate the BF algorithm using synthetic data generated with MCNPX-PoliMi for a simulated Compton imager consisting of a 4 x 7 array of LYSO scintillator crystals. Two independent sources are simulated, one sweeping in azimuth and one in elevation, each traveling from -90° to +90° at 1 m/s. The BF algorithm successfully tracked both sources across the full angular sweep, achieving mean angular errors of 6.4° and 6.03° for the azimuth and elevation cases, respectively. Additionally, preliminary results for multi-source tracking are successful with the algorithm tracking both sources up until their paths intersect which is a known challenge we are currently investigating.

Abstract

Radiomics analysis in total-body PET imaging is highly sensitive to acquisition variability, particularly count reduction, which directly affects noise characteristics and feature reliability. In this study, we investigate the impact of count reduction and multi-parametric harmonization on the robustness of multi-organ radiomics. A retrospective

dataset of 550 patients from two centers was analyzed. Multiple count levels were generated from list-mode data, including standard and reduced counts (reduction factors up to 100). Multi-organ segmentation was performed automatically, and 107 IBSI-compliant radiomics features were extracted from SUV-normalized images. Feature harmonization was applied using ComBat under different configurations, including scanner, voxel size, radiopharmaceutical, and scatter correction. Reproducibility was evaluated using intraclass correlation coefficients across count levels and anatomical regions. Results show that radiomics stability is strongly dependent on both count level and feature type. Approximately 31% of features achieved good reproducibility (ICC ≥ 0.75) in at least one organ. Shape and first-order features remained relatively stable under moderate count reduction (CRF ≤ 20), while higher-order texture features exhibited substantial degradation at extreme count levels (CRF ≥ 50). Harmonization improved feature consistency, particularly for scanner- and resolution-related variations, but had limited impact under severe noise conditions. Taken together, the results indicate that preserving quantitative reliability in low-count PET requires careful consideration of both feature selection and acquisition variability. Rather than relying solely on harmonization, robust radiomics analysis should incorporate count-aware strategies, especially when extending to multi-center or ultra-low-count imaging scenarios.

Development of a Single-Layer Dual-Ended Readout Compton Camera Prototype for Enhanced Spatial Imaging (#1799)

Haoqi Wen, Chenxi Li, Yucun Hou, Kexin Wang, Jianyong Jiang

Beijing Normal University, Key Laboratory of Beam Technology of Ministry of Education, School of Physics and Astronomy, Bejing, China

This work was supported by the NSFC (No. 12475336).

Abstract

The Compton camera has emerged as a pivotal gamma-ray imaging technique, with critical applications in astrophysical observation, nuclear safety monitoring, and environmental radiation detection. In nuclear astrophysics, the detection and localization of gamma rays in the MeV range are indispensable for probing high-energy cosmic phenomena. Despite its importance, the advancement of MeV gamma-ray imaging instrumentation remains constrained by low interaction probabilities and high imaging complexity. This study presents a single-layer Compton camera prototype designed for enhanced spatial imaging, building upon the mission heritage of the BNU-120—a space-borne detector successfully deployed for monitoring gamma-ray bursts (GRBs). To transcend the original system's lack of spatial imaging capability, we propose a high-performance architecture that leverages the established BNU-120 framework while integrating a dual-ended readout to achieve a 4π detection solid angle. The prototype uses a 8×8 Ce:GAGG array coupled to Hamamatsu Multi-Pixel Photon Counters (MPPC, S14161-3050HS-08) at both ends. Each crystal measures 3×3×25 mm^3 and is optically isolated by 0.2-mm-thick $BaSO_4$ reflective layers. System characterization demonstrated an energy resolution of approximately 5% (FWHM) at 511 keV. Depth-of-interaction (DOI) information, extracted via the energy ratio method, yielded a DOI resolution of roughly 2 mm (FWHM) along the crystal axis. Computational validation using GATE simulations of a U-shaped 511

keV planar source showed that the source geometry was clearly distinguishable through a back-projection (BP) algorithm. Subsequent point-source experiments verified the detector's capability to localize discrete sources. Future work will focus on realistic physical imaging experiments and the exploration of more advanced reconstruction algorithms to fully evaluate the module's Compton imaging performance.

Abstract
Precision physics at future e+e− Higgs factories set stringent requirements on calorimetric performance, with 3%/√E for electromagnetic particles and ∼ 30%/√E for neutral hadrons identified as key benchmarks. A hybrid dual-readout approach, combining a homogeneous crystal electromagnetic section with a fiber-based hadronic section, offers a cost-effective path toward simultaneously achieving both targets. Reaching such performance requires enhancing the longitudinal and transverse granularity of the crystal section beyond what is available in conventional

homogeneous calorimeters and equipping each crystal cell with two independent readout channels to simultaneously collect Cherenkov and scintillation light. These features enable advanced particle-flow dual-readout reconstruction algorithms to exploit the maximum available information from each event. This work will present extensive laboratory characterizations together with beam-test measurements carried out at CERN on single-crystal PWO, BGO, and BSO cells instrumented with optical filters and SiPMs. These studies demonstrate event-by-event separation of Cherenkov and scintillation light, with both scintillation and Cherenkov yields exceeding the thresholds required for optimal electromagnetic and hadronic energy resolution. The results have guided the technological choices for the ongoing construction of full-containment calorimeter prototypes

Design of the ePIC Hadronic Barrel Calorimeter, Status of the Test stand and Prospects for Physics at the EIC. (#2964)

Eric J. Mannel

Brookhaven National Laboratory, Physics Dept, Upton, USA

This work is supported by the United States Department of Energy.

Abstract
ePIC is the general purpose detector for the Electron-Ion Collider (EIC) that is being built at Brookhaven National Laboratory and will be ready for first physics when the Electron-Ion Collider turns on. ePIC is based on a new 1.7T superconducting solenoid magnet. The detector consists of precision tracking, particle identification and calorimeter (electromagnetic and hadronic) to measure the properties of electron-Ion collisions that will occur at the EIC. In this paper we will present the over all design of the ePIC detector, with a focus on the Barrel Hadronic Calorimeter (BHCal) which is the repurposed sPHENIX Outer Hadronic Calorimeter (HCal). We will also present the current status of the BHCal design, test stand and preliminary results of the new electronics readout system based on the CaloROC chip designed for ePIC

N-LT-04-13

Off-detector Readout and Real-time Signal Processing for the ATLAS Liquid ArgonCalorimeter at the High-Luminosity LHC (#2635)

Pablo Collado Soto[2], **Nikiforos Nikiforou**[1], On behalf of the ATLAS Collaboration

[1] CERN, Geneve, Switzerland; [2] Universidad Autonoma de Madrid, Physics Department, Madrid, Spain

Abstract

The ATLAS Liquid Argon (LAr) calorimeter readout electronics are being upgraded for operation at the High-Luminosity Large Hadron Collider (HL-LHC), where up to approximately 200 proton-proton interactions per bunch crossing will significantly increase detector occupancy, data throughput, and trigger rates. While the calorimeter detectors themselves remain unchanged, the full readout electronics chain is being replaced. The upgraded off-detector processing system continuously receives digitized calorimeter signals from approximately 182000 channels at the 40 MHz bunch-crossing rate through high-speed optical links. The processing architecture is implemented in Advanced Telecommunications Computing Architecture (ATCA) systems hosting large FPGAs performing real-time reconstruction of energy and timing while satisfying stringent trigger latency requirements. Prototype hardware and firmware have been developed and validated in integration setups combining front-end electronics, timing distribution, and data acquisition systems. In parallel, advanced reconstruction methods including machine-learning approaches optimized for FPGA implementation are being investigated to improve robustness against pileup and overlapping pulses.

N-LT-04-14

The LS3 Enhancement of the LHCb Electromagnetic Calorimeter (#2898)

Eduardo Picatoste[1], Sergio Gómez[2], on behalf of the LHCb ECAL Upgrade II RD Group

[1] Universitat de Barcelona, Institute of Cosmos Sciences of the University of Barcelona, Barcelona, Spain; [2] Universitat Politècnica de Catalunya, Barcelona, Spain

Abstract

An upgrade of the LHCb electromagnetic calorimeter (ECAL) is planned for Long Shutdown 3 (LS3) to address significant aging effects in the central region caused by radiation damage and high particle flux. The innermost ECAL modules will be replaced with a new design based on Spaghetti Calorimeter (SpaCal) technology, optimized for radiation tolerance and improved performance under high occupancy conditions. A total of 176 SpaCal modules will be installed. These are based on scintillating plastic fibers embedded in dense absorbers. The innermost 32 modules will use 3D-printed tungsten absorbers to withstand the highest radiation levels, while the remaining 144 modules will employ lead absorbers produced through an innovative casting technique. Both configurations have

been prototyped and extensively validated in test beam campaigns at DESY-II and CERN SPS. The measured energy resolution for electron beams is consistent with performance requirements and shows good agreement with detailed Monte Carlo simulations. The scintillating fibers will be read out using radiation-hard hollow light guides coupled to fast photon detectors. In total, 3072 new readout channels will be implemented with dedicated front-end electronics. In parallel with the installation of the new SpaCal modules, the current Shashlik calorimeter modules will be rearranged to better match the spatial distribution of particle occupancy. Simulation studies demonstrate a significant reduction in per-cell occupancy after the LS3 upgrade, improving detector performance in Run 4 conditions. Benchmark analyses of key physics channels confirm that this enhancement leads to a substantial gain in reconstruction efficiency and measurement precision. Overall, the LS3 ECAL upgrade represents a crucial step toward coping with higher luminosity conditions and anticipates key design features of the future PicoCal system foreseen for implementation during LS4.

Gas Circulation and Pressure Protection System for the COMET Cylindrical Drift Chamber (#1762)

Ryo Nagai[1], Shukei Kawano[1], Shunya Ueda[1], Yuuki Nakano[2], Akira Sato[1], Kazuki Ueno[1]

[1] The University of Osaka, Department of Physics, Osaka, Japan; [2] University of Toyama, Faculty of Science, Toyama, Japan

This work was supported by JSPS KAKENHI Grant Number 21H04971.

Abstract

The COMET Cylindrical Drift Chamber is a large, low-mass gaseous detector. Gas exchange through the detector volume affects gas quality, gain stability, and wire aging, which are important for stable detector operation. Increasing the gas-flow rate in a once-through operation would increase fresh-gas consumption and cost, and would also impose constraints on exhaust handling from the experimental area. For this reason, a gas circulation system is adopted. At the same time, safe operation of the chamber requires the differential pressure between the chamber volume and the surrounding atmosphere to be maintained within a narrow range, because the large-radius, low-mass inner wall adopted to suppress backgrounds imposes a strict mechanical limit on the allowable differential pressure. Pressure excursions caused by pump operation, environmental variations, or abnormal exhaust conditions must be suppressed. While the system consists of standard gas-system components, their configuration and operating parameters were quantitatively evaluated against the mechanical constraints and gas-flow requirements of the chamber. A simplified analysis based on a resistance-compliance model was introduced to interpret pressure propagation in the gas system. Preliminary gas-system commissioning tests, including pump-start and exhaust-transient measurements, were performed to characterize the pressure response and to evaluate the roles of buffer tanks and restricted flow paths. The results are being used to define the buffer-tank configuration, emergency-exhaust conductance, pump operating conditions, and a staged gas-commissioning procedure, enabling safe commissioning and stable long-term operation of the detector.

Abstract

In this work, we present a systematic characterization of a 2D-THCOBRA detector operated in pure argon (Ar) and Ar/Xe mixtures (Ar/Xe 98/2, 95/5 and 90/10), exploiting the Penning effect to enhance detector performance. The detector is characterized in terms of gain, energy resolution, linearity, and intrinsic spatial resolution. The addition of Xe to Ar significantly reduces the required operating voltage, with equivalent gains achieved at voltages approximately 300 V lower than those required for pure Ar. The energy resolution improved from 24.4% (pure Ar) to 18.3% FWHM at 5.9 keV (Ar/Xe 95/5 mixture), and the intrinsic spatial resolution improves from 1.8 mm (pure Ar) to 1.5 mm FWHM Ar/Xe 95/5. These initial results demonstrate the strong potential of the 2D-THCOBRA operating in Ar/Xe mixtures for X-ray fluorescence imaging and spectral X-ray imaging applications.

The effect of hole geometry on the ion-backflow of a single gas electron multiplier foil (#2631)

Hussam Badran[1], **Erik Brücken**[1,2], Jouni Heino[1], Timo Hildén[1]

[1] Helsinki Institute of Physics, Helsinki, Finland; [2] University of Helsinki, Department of Physics, Helsinki, Finland

Abstract

A systematic study of the ion-backflow (IBF) contribution of single GEM foils with respect to the hole sizes and geometries is presented. The effective gain and the IBF of single GEM foils in a standard gas enclosure with a 2D strip readout plane were measured, using Ar-CO2 (70-30) gas mixture. The X-ray exposure using ^{55}Fe source was performed separately for each foil segment to compare the performance differences of the different hole geometries. A clear dependency of the IBF to the size and shape of the GEM holes was found. The results were compared to simulations using the Garfield++ toolkit. We present that choosing the right foils for a TPC readout chamber can effectively limit the IBF.

Abstract

A compact SiPM–GAGG(Ce) radiation detector without conventional front-end electronics was evaluated for LINAC radioactivation monitoring. The proposed detector employed a simplified signal-processing architecture without a preamplifier, shaping amplifier, or comparator. Spectroscopic performance was evaluated at SiPM operating voltages from 58 V to 61 V. The best energy resolution for the 662 keV photopeak of Cs-137 was 8.31% at 61 V, corresponding to an overvoltage of approximately 7 V from the measured breakdown voltage of 53.88 V. Mixed-source measurements using Ba-133, Cs-137, and Co-60 demonstrated distinguishable radionuclide peaks and channel-energy linearity greater than 0.99. The detector was subsequently applied to LINAC radioactivation measurements, where characteristic gamma-ray peaks of W-187 were successfully detected near the LINAC head after high-energy photon beam irradiation. The results demonstrate the feasibility of compact and simplified LINAC radioactivation monitoring using the proposed detector system.

Temperature Dependence of Energy Resolution in a SiPM-Based Scintillation Detector for PET Applications (#1177)

Solano Rigotti Caiano[1], Daniel Alexandre Baptista Bonifacio[1], Helio Massaharu Murata[1], Marcio Bottaro[2], Mauricio Moralles[1]

[1] University of São Paulo (USP), Institute of Energy and Nuclear Research (IPEN), São Paulo, Brazil; [2] University of São Paulo (USP), Institute of Energy and Environment (IEE), São Paulo, Brazil

Abstract

Silicon photomultipliers (SiPMs) are widely used in PET detectors due to their compact size and compatibility with magnetic fields. However, their performance is strongly dependent on temperature. In this work, the temperature dependence of energy resolution in a SiPM-based scintillation detector coupled to a LYSO crystal is experimentally investigated. Measurements were carried out over a temperature range from 10 to 50 degrees Celsius using a controlled climatic chamber. Preliminary results show a systematic degradation in energy resolution with increasing temperature. A simplified physical interpretation based on the temperature dependence of breakdown voltage,

gain, photon detection efficiency (PDE), and noise contributions is proposed. Ongoing work focuses on developing a quantitative model and compensation strategies for detector stabilization.

Development of transparent ceramic Tl:NaI scintillators for gamma-ray detectors (#1187)

Takayuki Yanagida, Takumi Kato, Daisuke Nakauchi, Noriaki Kawaguchi

Nara Institute of Science and Technology, Ikoma, Japan

This work was supported by the Cooperative Research Project of Research Center for Biomedical Engineering, Kazuchika Okura Memorial Foundation, Yashima Environment Technology Foundation, Iketani Science and Technology Foundation, and JSPS KAKENHI (22H00309, 24K03197, and 26K03208).

Abstract

Tl-doped NaI (Tl:NaI) single crystal has been a one of the standard scintillators from mid 20th century, and in this time, we will report a development of transparent ceramic Tl:NaI. Tl 0.05, 0.1, 0.3, and 0.5% doped NaI transparent ceramics were fabricated by the spark plasma sintering (SPS) method. Under X-ray irradiation, these ceramics showed a typical emission wavelength at 420 nm with a typical decay time (~200 ms) due to $^3P_1 \rightarrow {}^1S_0$ electronic transitions of Tl^+. When 662 keV gamma-rays from 137Cs were irradiated, all the samples exhibited a clear photoabsorption peak, and among all the samples, 0.1% doped one had the highest scintillation light yield, reaching to 36000 ph/MeV, which was equivalent to common commercial Tl:NaI single crystal.

Simulation of Electron Escape within Thin Organic Scintillators (#1248)

Ethan Schneider, Colton Graham, Erin Neely, David Breitenmoser, Shaun D. Clarke, Sara A. Pozzi

University of Michigan, Ann Arbor, USA

This work was supported in part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration, award number DE-NA0003920.

Abstract

Organic scintillators are fast detectors that are sensitive to both neutrons and gamma rays. Measurements of neutron timing in an intense gamma-ray field can be studied with thin organics, as recoil electrons produced by Compton scatters have a path length significantly longer than those of recoil protons. Past work in characterization of such samples has been hindered by the lack of clear energy calibration with samples with thicknesses less than 2 mm, as the spectral features used for an energy calibration are significantly broadened from electron escapes. To address this issue, the gamma spectrum was observed for three gamma check sources, Cs-137, Na-22, and Co-60, within four organic glass scintillators, from 6 mm to 1 mm, and compared with Monte Carlo models MCNPX-PoliMi. A genetic algorithm was used to broaden the simulated spectra to match the measured spectra. Thinner samples displayed greater broadening of Compton edges, which suggests an increase in electron escape. Simulations show an increase in electron escape probability between the 6 mm sample and the 1 mm sample of 12% ± 1% to 26.1% ± 0.3%.

Alignments of the Dual-Layer Flat-Panel Detectors and their Modulation Transfer Functions (#1465)

Dong Sik Kim

Hankuk University of Foreign Studies, Division of Semiconductor and Electronics Engineering, Sungnam, South Korea

This work was supported by the National Research Foundation of Korea (NRF) grants funded by the Korean government (MSIP) (No. RS-2024-00459219).

Abstract

In radiographic imaging, dual-layer flat-panel detectors (DFDs) can be used for two purposes: acquiring high-quality x-ray images and performing material decomposition.

A convex combination of the x-ray images acquired from DFD can yield significantly improved detective quantum efficient. The DFD structure consists of stacked upper and lower flat-panel detectors, and can provide different modulation transfer function (MTF) characteristics depending on the orientation of the stacked detectors with respect to the incident x-ray. In this paper, we consider three different stacked structures for DFD and find the optimal DFD structure by experimentally observing the MTF curves using fabricated DFD prototypes. Because the inverted layers have a back-irradiation geometry, the MTF performance is better than that of the normal case. Therefore, we can select a DFD structure having an inverted lower layer to acquire high-DQE x-ray images.

Loading Surface-Modified $LiAlO_2$ Nanoparticles in Plastic Scintillators for Thermal Neutron Detection (#1484)

Haruhisa Tsukahara[1], Kenichi Watanabe[2], **Masanori Koshimizu**[1,3]

[1] Shizuoka University, Graduate School of Integrated Science and Technology, Hamamatsu, Japan; [2] Kyushu University, Department of Applied Quantum Physics and Nuclear Engineering, Fukuoka, Japan; [3] Shizuoka University, Research Institute of Electronics, Hamamatsu, Japan

Abstract
We report the development of plastic scintillators for thermal neutron detection by incorporating surface-modified $LiAlO_2$ nanoparticles. Conventionally, thermal neutrons have been detected using ^{3}He gas counters, but the scarcity of ^{3}He has driven the search for alternative technologies. Plastic scintillators are attractive due to their low cost and ease of fabrication; however, loading neutron-reactive isotopes such as ^{6}Li into plastics is challenging because conventional organometallic compounds suffer from poor solubility and strong quenching effects.
To overcome these limitations, $LiAlO_2$ nanoparticles enriched with ^{6}Li were synthesized via a sol–gel method and their surfaces were modified with trimethoxyphenylsilane to improve compatibility with a polystyrene matrix. Structural and spectroscopic analyses confirmed that the nanoparticles retained the γ-$LiAlO_2$ phase and were successfully functionalized with phenyl groups, without significant changes in particle size. The surface modification greatly enhanced nanoparticle dispersion within the plastic scintillator, as evidenced by uniform elemental mapping.Scintillation measurements demonstrated that the emission originated from the organic fluor and that the modified nanoparticles did not introduce additional emission bands. The scintillation light yields of 2400–3000

photons per neutron were achieved, depending on nanoparticle loading, which is substantially higher than those of boron-loaded commercial plastic scintillators and plastics containing unmodified $LiAlO_2$ nanoparticles. These results highlight surface modification as an effective strategy for improving the performance of nanoparticle-loaded plastic scintillators for thermal neutron detection.

Development of Perovskite Quantum Dots with High Photoluminescence Quantum Yields and Their Loading in Plastic Scintillators (#1618)

Itsutoshi Ishihara[1], Kazuki Asou[1], **Masanori Koshimizu**[1,2]

[1] Shizuoka University, Faculty of Engineering, Hamamatsu, Japan; [2] Shizuoka University, Research Institute of Electronics, Hamamatsu, Japan

Abstract

Fast plastic scintillators are attractive for radiation detection owing to their nanosecond decay times, low cost, and scalability; however, their practical application is limited by low scintillation light yield and poor detection efficiency for X- and γ-rays. In this study, we report the development of plastic scintillators loaded with perovskite quantum dots (QDs) exhibiting high photoluminescence quantum yields (PL QYs). Cesium lead halide perovskite QDs with various halogen compositions were synthesized via a facile solution process under ambient conditions. Surface modification using oleyl amine was employed to passivate surface defects and enhance radiative recombination. Transmission electron microscopy revealed spherical QDs with diameters of approximately 10 nm and a narrow size distribution. The oleyl amine modification markedly improved PL QYs, achieving values exceeding 80% for $CsPbBr_3$ QDs. By tuning the halogen composition, the emission wavelength was controllably varied from ~420 to 540 nm. These high-PL-QY QDs were uniformly loaded into polystyrene-based plastic scintillators. Scintillation spectra demonstrated dominant QD emission without defect-related luminescence, indicating fast emission owing to the interband transition within the QDs. Although clear full-energy peaks were not observed in pulse-height spectra, enhanced scintillation responses were evident for samples containing surface-modified QDs. These results demonstrate that surface-engineered perovskite QDs are promising additives for improving the performance of fast plastic scintillators.

Effect of geometry on the properties of 3D-printed scintillators (#1708)

Vivek Anand, Anjali Sharma, Utkarsh Bajpai, Bhavika Bansal, Anil K. Gourishetty

Indian Institute of Technology Roorkee, Roorkee, India

This work was supported by the Ministry of Higher Education (MHRD), Government of India.

Abstract

This work investigates how scintillator geometry influences light collection in 3D-printed plastic scintillators, motivated by the ability of additive manufacturing to fabricate detector shapes that are difficult to realize by conventional casting or machining. Four geometries, including a cylinder, truncated cone, cone, and paraboloid, were fabricated using a digital light processing based 3D printing method and evaluated experimentally. Complementary Geant4 optical-photon simulations were performed to study photon transport and collection trends for the same geometry family. Both experiment and simulation indicate that geometry modifies photon escape, internal reflection, and collection at the readout face. Taking the cylinder as the reference at 100%, the truncated cone, paraboloid-like geometry, and cone show increased relative light outputs of 151%, 156%, and 180%, respectively, suggesting that non-cylindrical 3D-printed scintillator shapes can improve photon collection at the readout face, most likely by reducing unfavorable optical paths and repeated reflections. The simulations reproduce the qualitative trend observed experimentally, although the absolute values do not agree number by number because the present model does not fully include fabrication-specific effects such as print-layer scattering, surface roughness, optical coupling variations, reflector response, and sensor nonuniformity. These results demonstrate that geometry is an important design parameter for additively manufactured scintillators and should be optimized together with material composition and photosensor coupling.

Abstract

In June 2025, Kori Unit 1, the first commercial nuclear power plant in the Republic of Korea, obtained final approval for decommissioning. This milestone highlights the growing need for radiation-imaging technologies that can support radiation surveillance during nuclear decommissioning and in other high-radiation environments. In this study, we developed a portable gamma camera for real-time monitoring of high-energy gamma-ray fields and evaluated its basic detector characteristics and imaging performance. The spatial response of the GAGG-SiPM detector array was investigated using flood-map measurements and line-profile analysis. The obtained flood maps showed that all scintillator pixels were distinctly resolved, with minimal signal overlap between adjacent pixels. The average full width at half maximum (FWHM) was measured to be approximately 0.58 mm, corresponding to about 41% of the 1.41 mm pixel pitch, indicating stable intrinsic spatial resolution across the detector array. The intrinsic energy resolution was assessed using a Co-60 point source. The measured energy resolutions were 7.42% and 6.68% FWHM at the 1.17 MeV and 1.33 MeV photopeaks, respectively. In addition, the detectable imaging distance was examined by acquiring Co-60 point-source images at source-to-detector distances from 10 cm to 300 cm. The source location was successfully identified throughout the tested range, and clear gamma-ray imaging was achieved even at a distance of 3 m. These results demonstrate that the proposed portable gamma camera provides stable detector response, high-energy gamma-ray imaging capability, and practical source-localization performance for radiation monitoring in nuclear decommissioning environments.

Abstract

A SiPM-based detector using GAGG powder-PMMA composite scintillators was developed and evaluated. There were 8 scintillator samples with the identical GAGG mass fraction but different powder grain sizes. Each scintillator has an active area of 40 mm × 40 mm and a total thickness of 3.6 ± 0.1 mm. The detector system consisted of the scintillator module, front-end analog electronics for filtering, shaping, and amplification, and an 8-channel back-end digital acquisition system. Under identical measurement conditions, the count rate measured with a 50 μCi 22Na source increased from approximately 1.7 × 10^3 cps for Sample #1 to 1.6×10^4 cps for Sample #8. Waveform measurements also showed higher output amplitude for the larger-powder sample. The results indicate that the grain size of GAGG powder strongly affects photon transport and effective detector response in the composite scintillators.

Abstract

We studied thermal neutron detection using a LiF/CaF_2:Dy eutectic composite which can be used for thermoluminescence dosimetry. Emissions of the sample due to the self-trapped exciton of CaF_2 and 4f-4f transitions of Dy^{3+} ions were confirmed in the X-ray excited spectrum and decay curve measurements. The thermoluminescence spectrum at 230 ℃ showed only the emission peaks due to Dy^{3+}. This result indicates that Dy-doping in LiF/CaF_2 is efficient for thermoluminescence dosimetry applications. Thermal neutron detection was performed using the LiF/CaF_2:Dy eutectic composite, and its light yield was 3000 photons/neutron. This measurement was achieved due to the fast emission of the self-trapped exciton. The LiF/CaF_2:Dy eutectic composite can act as a dual functional material for radiation dosimetry and detection.

Abstract

Scintillation detectors are widely used in various fields. Since the performance of scintillators directly affects detector properties, the evaluation of scintillation properties is essential. Scintillators are required to exhibit specific properties, including a high light yield, a short decay time, and a low afterglow. So far, afterglow measurements have not yet been standardized, and each manufacturer employs its own measurement setup and evaluation criteria. In conventional systems, their temporal resolution is limited to several milliseconds, which is insufficient for accurate characterization of afterglow in the short-time region. Separately, although near infrared (NIR)-emitting scintillators have recently attracted considerable attention and their emission spectra have been investigated, their NIR decay curves have not been sufficiently evaluated. In this study, we developed the afterglow and NIR decay curve measurement systems by combining a field-emission pulse X-ray source with the two types of detection units: an afterglow detection unit and an NIR detection unit. The performance of the developed system was evaluated by measuring the afterglow of CWO, BGO, and CsI:Tl, as well as the NIR decay curve of the NIR-emitting Yb:Lu_2O_3 transparent ceramics. The afterglow levels of CWO, BGO, and CsI:Tl were approximately 2.5, 0.5, and 450 ppm, respectively. The X-ray-induced NIR decay time constants of 0.1%–3.0% Yb:Lu_2O_3 transparent ceramics were 0.66–1.05 ms. Since these values were comparable to previously reported afterglow levels and PL decay time constants, the present results are considered to be valid.

One Dimensional TPE-4Br Supramolecular Scintillator for High-Speed X-ray Imaging (#2373)

Xiaoqing Liu[1,2]

[1] Wuhan University of Technology, State key Laboratory of Advanced Glass Materials, Wuhan, China; [2] Wuhan University of Technology, School of Materials Science and Engineering, Wuhan, China

This work was supported in part by the National Natural Science Foundation of China (U2330115, 62134003, 62275206) and National Key Research and Development Program of China (2024YFE0217100)

Abstract

Next-generation radiation detection, such as TOF-PET and high-flux X-ray imaging, requires scintillators that combine high light yield with ultrafast response. However, organic scintillators are often limited by inefficient exciton utilization and non-radiative quenching of high-energy states. In this work, we report a 1D supramolecular organic architecture based on the luminophore TPE-4Br. By shifting the molecular packing from a discrete 0D form into an ordered 1D configuration, we achieve a structural "locking" effect that rigidifies the lattice and suppresses vibrational quenching. This configuration results in an increase in Young's modulus (6.44 GPa) and hardness (0.24 GPa) compared to 0D crystals. Under X-ray excitation, the 1D framework exhibits an enhanced light yield that is 1.5 times higher. Furthermore, real-time dynamic X-ray imaging at 67 fps is demonstrated, showing minimal afterglow and the ability to track moving objects with high signal fidelity. This combination of luminosity, timing, and mechanical robustness positions the TPE-4Br-based 1D framework as a candidate for high-speed nuclear instrumentation and medical CT systems

Development of a Large-Area Diode-Multiplexed Scintillation Detector for Prompt Gamma Monitoring in Proton Therapy (#2409)

Xiaodong Mo, Chunhui Zhang, Xiangdong Cai, Yongzhi Yin

Lanzhou University, School of Nuclear Science and Technology, Lanzhou, China

Abstract

This work presents the development of a large-area flat-panel scintillation detector designed for prompt gamma monitoring in proton therapy. The detector comprises a 2x2 of ArrayJ-60035-64P silicon photomultiplier arrays, coupled with a 14x14 Lutetium-yttrium oxyorthosilicate crystal array. To address the challenge of high channel density, a diode-based row-column multiplexing circuit was implemented, reducing the total number of readout channels from 256 to 64. The system interfaces with the PETsys TOFPET2 ASIC via a custom adapter board utilizing LSHM-140 connectors. Preliminary laboratory tests using a 22Na point source demonstrate the feasibility of the multiplexing scheme and its potential for high-resolution gamma-ray imaging in clinical environments.

Development of a Hand-Foot Monitor for Visualizing Alpha Contamination (#2451)

Naoki Sagawa

Japan Atomic Energy Agency, Plutonium Radiation Control Section Radiation Protection Department, Muramatsu, Tokai-Mura, Naka-Gun, Japan

This work was supported by JAEA Nuclear Energy S&T and Human Resource Development Project Grant Number JPJA25P 25135771.

Abstract

When exiting controlled areas such as nuclear facilities, contamination control is of the utmost importance to prevent the removal of contaminants outside the area. Currently used hand and foot monitors and personnel contamination monitors are equipped with multiple detectors near the clothing and limbs, enabling the simultaneous measurement of radioactive contamination on the body surface.
However, conventional detectors make it difficult to pinpoint contaminated areas in detail. Accurately visualizing contamination distribution is crucial for preventing internal exposure and conducting efficient decontamination operations.

This study aimed to develop a personnel contamination monitor capable of visualizing contaminated areas. Contamination visualization is achieved by combining an electron-multiplying charge-coupled device (EMCCD) camera or a quantitative complementary metal-oxide-semiconductor (qCMOS) camera with multiple scintillators, such as ZnS(Ag) scintillators and rare-earth complex high-luminescence scintillators.
This device utilizes a CCD camera (ImagEMX2, Hamamatsu Photonics K.K.) or a CMOS camera (ORCA-Quest, Hamamatsu Photonics K.K.) in combination with a 3.25 mg/cm² ZnS(Ag) scintillator (EJ-440, Eljen Technology), a rare-earth complex high-luminescence scintillator (manufactured by Hokkaido University), and a large-area plastic scintillator containing dispersed europium complexes (manufactured by Hokkaido University). The system was irradiated with alpha rays, and the resulting images were analyzed using ImageJ.As a result, the luminous intensities of the various scintillators were confirmed, and we were able to select the optimal combination of scintillators and device configuration conditions for visualizing contaminated areas.

Room-Temperature Synthesis of Na^+-Doped $Cs_3Cu_2I_5$ Single Crystals: Structural, Optical and Scintillation Properties (#2545)

Bhavika Bansal[1], Anil K. Gourishetty[1]

[1] Indian Institute of Technology Roorkee, Department of Physics, Roorkee, India; [2] Indian Institute of Technology Roorkee, Department of Physics, Roorkee, India

Abstract
Copper-based halide perovskite $Cs_3Cu_2I_5$ has emerged as a promising lead-free scintillator for ionizing radiation detection. In this work, Na^+-doped and undoped $Cs_3Cu_2I_5$ single crystals were grown at room temperature via a formic-acid-assisted solvent evaporation method. Both crystals exhibit ordered diffraction planes and excellent crystallinity, confirmed by rocking-curve full width at half maximum (FWHM) values of 0.009° (undoped) and 0.008° (Na^+-doped). X-ray photoelectron spectroscopy confirms that Cu^+ remains in its monovalent state in both samples. Optical analyses show that Na^+ incorporation enhances the photoluminescence (PL) intensity by 11% and increases the self-trapped exciton (STE) decay time from 1090 ns to 1146 ns, attributed to shallow defect passivation and suppressed non-radiative recombination. The Na^+-doped crystal demonstrates superior scintillation performance with a light output of 42,000 ph/MeV and an energy resolution of 4.9% at 662 keV, compared to 39,000 ph/MeV and 5.4% for the undoped crystal, corresponding to improvements of ~7.6% and ~9%, respectively. These results establish Na^+ doping as an effective strategy for defect suppression and scintillation enhancement in lead-free halide perovskite single crystals.

Thermal Cycling of Optical Coupling Material to Investigate Performance Degradation in Detectors (#2575)

Zoe H. Sharpe[1,2], **Kerri L. Loughney**[1,2], Chris Allwork[1,2], Paul J. Sellin[2]

[1] AWE NST, Reading, UK; [2] University of Surrey, Physics, Guildford, UK

Abstract

Thermal cycling is used to accelerate the ageing process through an exaggerated version of diurnal temperature variations a detector/material may experience during use/storage over the lifetime of a detector. For this investigation, samples of optical grease were thermally cycled between +5 and +75°C in an environmental chamber. Four sets of samples were created with different preparation methods, volumes and substrates used, consisting of: 0.02g between microscope slides, 2ml petri dish, and 1” & 2” diameter discs in petri slides. A total of 15 samples per set were created that were divided into three subsets: Cyclical (C), Duration (D) and Room (R) samples. The percentage transmission (%T) for all samples was measured using a spectrophotometer for a wavelength range of 300-700nm for comparison with the emission range of common scintillators, such as EJ200. Identical “blank” samples with air were used for baseline/zero corrections performed for the spectrophotometer, meaning all %T values are relative to air. C samples were recharacterised at the end of each year equivalent cycle, while D and R were only recharacterised after the final cycle as controls for the removal from the chamber and the passage of real time respectively. Samples were cycled to equivalent of a maximum 20 years, with an additional set of “no bubble” (NB) samples introduced at the start of the 11th year equivalent cycle to determine the impact of air bubbles on %T. The 1” petri slide samples displayed the greatest average variation in %T across the range 400-500nm, with a drop of 20% %T value between pre and post-20 year characterisation (28% percentage difference), while 2” petri slide samples showed an average 10% decrease in %T value (15% percentage difference). Microscope slides and petri dish samples displayed a 2.6% average %T decrease (3% percentage difference) and 3.9% average %T increase (4.7% percentage difference) respectively.

Abstract

Scintillators play an important role in radiation detection and imaging. Thallium-doped cesium iodide (CsI:Tl) is one of the major scintillators that have been used for many applications for many decades. Coupling CsI:Tl crystals to silicon photomultipliers (SiPMs) makes them into compact and portable detectors, enabling them to be incorporated in many modular detector designs. This paper presents a performance study of improved CsI:Tl crystals coupled to silicon photomultipliers (SiPMs). Iterations of electronic designs as well as CsI:Tl crystal growth, processing, and characterization with both photomultiplier tubes (PMTs) and SiPMs will be presented.

Abstract

Scintillator energy resolution is ultimately limited by light yield. One theoretical pathway for increasing this light yield in inorganic scintillators is optical re-excitation of activator ions. $Lu_3Al_5O_{12}$ (LuAG) with Ce^{3+} activator ions is investigated as a candidate for verifying the mechanism. Ca co-doping is used to convert the Ce^{3+} to Ce^{4+} during manufacturing, so Ce^{3+} is only present in the material after a radiation interaction occurs, allowing for multiplication of the radiation-induced signal. Optical spectroscopy is used to evaluate the impact of co-doping ratios on the concentration of Ce^{4+} in several samples. The impact of
stimulation wavelength on the intensity of previously observed optically-induced valence change indicates the valence change originates from charge-transfer absorption of the Ce^{4+}. A dual-beam optical and x-ray excitation experiment with a chopperwheel and lock-in amplifier is used to compare the scintillation response of LuAG:Ce and LuAG:Ce,Ca samples to single- and dual-beam excitation. The difference between these responses is evaluated with a lock-in amplifier and using a program which superimposes the single-beam signals and minimizes the variance of this superposition with respect to the dual-beam signal. After optical characterization, the responses of LuAG samples with different Ce concentrations and co-doping ratios will be tested in this dual-beam experiment to identify optimal doping concentrations for re-excitation.

Study of elpasolite crystals for neutron/gamma spectroscopy : First measurements with CLYC:Ce (#3212)

Isaac Zeghni, Clément Delafosse

CNRS, IJCLab, Orsay, France

This project has received funding from the French Agence Nationale de la Recherche under grant agreement No. ANR-24-CE31-7626-01 (ANR SENSE).

Abstract

The spectroscopy of decay products is one of the three pillars of low-energy beam exploitation techniques produced by the ISOL method. Decay stations can be found in all facilities using the ISOL technique to produce radioactive beams, such as ALTO (France), ISOLDE (CERN), and IGISOL (Finland), as well as in future facilities like SPES (Italy) and DESIR (France), to name a few in Europe.

In the context of β decay, it is important to note that the total energy released during this process, denoted as Q_β, can exceed 10 MeV as we venture further from nuclear stability. At the same time, the energy required to remove a neutron (S_n) decreases, resulting in the emission of unbound neutron(s) alongside the expected γ-rays.

Elpasolite crystals containing ^{35}Cl such as CLYC:Ce represent a promising way to detect and discriminate both neutrons and γ-rays coming from such decay while measuring their energies. The ANR project SENSE (Scintillating Elpasolite for Neutron Spectroscopy Enhancement) aims to study such crystals using detailed Geant4 simulations in association with experimental measurements.

We started this project using a 3"x4" CLYC:Ce crystal in order to measure several physical quantities such as its resolution, efficiency and homogeneity. Those measurements were first performed for gamma only and are combined with simulations performed via Geant4 for comparaison. So far, the study of neutron interaction with the crystal is being studied and experiments using ALTO facilities are planned. Also, Geant4 does not implement well the cross-section of neutron interacting with chlorine and this part of the work is still in progress. Our presentation will share the results we have obtained for this CLYC crystal and the on-going work that is performed at IJCLab.

A feasibility study on CsPbBr3 perovskite crystals for time-of-flight PET (#1120)

Heejong Kim[1], Yingjie Wang[1], Subramanian Sundramoorthy[2], Mythra V. Nemallapudi[1], Chin-Tu Chen[1], Chien-Min Kao[1]

[1] University of Chicago, Department of Radiology, Chicago, USA; [2] University of Chicago, Department of Radiation and Cellular Oncology, Chicago, USA

Abstract

We are evaluating the potential of $CsPbBr_3$ crystals as Cherenkov light generating materials for TOF PET applications. $CsPbBr_3$, a lead halide perovskite semiconductor, has recently emerged as a highly efficient and cost-effective alternative to traditional radiation detection materials such as CZT and CdTe for X-ray and gamma-ray imaging. Its high carrier mobility and excellent energy resolution characteristics make it attractive for next generation radiation detector technologies. Furthermore, its high refractive index (~2.4) enables efficient generation of Cherenkov light, positioning this material as a promising candidate for fast timing applications, including TOF PET. To assess its timing performance, we investigated the coincidence time resolution (CTR) of $CsPbBr_3$ samples. Two crystal sizes—5 × 5 × 10 mm^3 and 3 × 3 × 3 mm^3—were used to study how crystal length affects CTR. Each crystal was optically coupled to a Broadcom NUV-MT SiPM (S4N44P014M or S4N66P014M) and irradiated with a ^{22}Na positron source in a coincidence timing measurement setup. A CTR of ~339 ps was achieved using a pair of 3 × 3 × 3 mm^3 $CsPbBr_3$ detectors. This preliminary result is highly encouraging and demonstrates the strong potential of $CsPbBr_3$ crystals for fast-timing radiation detection applications. In this work, we present our initial findings and discuss the associated challenges, along with potential strategies for further improving the CTR.

From Collision Cascades to Device Response: A Multiscale Study of Proton-Induced Defects in Silicon (#1178)

Sarah Shoorian, Hamid Jafari

Shahid Beheshti University, Nuclear Engineering, Tehran, Iran

In memory of Dr. Seyed Amirhossein Feghhi

Abstract

This study presents a comprehensive multi-scale computational and experimental investigation into displacement damage effects induced by high-energy proton irradiation in silicon-based photodiodes. The developed methodology systematically integrates SRIM-based analysis of primary knock-on atom (PKA) energy spectra, molecular dynamics (MD) simulations using LAMMPS to model atomic-level defect formation, and TCAD-based device-level electrical modeling in SILVACO. MD simulations revealed a nonlinear increase in stable Frenkel pair formation, ranging from minimal defects at low PKA energies (≤200 eV) to substantial defect clustering at higher energies (≥500 eV), with approximately 40 stable defects per 2 keV event. These atomistic results were used to inform TCAD models, which demonstrated that increasing mid-gap trap densities significantly amplify reverse-bias leakage currents via trap-assisted recombination mechanisms, consistent with the Shockley–Read–Hall (SRH) recombination theory. Experimental validation using BPX65 photodiodes irradiated with 3 MeV protons, corroborated simulation predictions. Leakage current increased dramatically with proton fluence, exhibiting linear trends at lower fluences. Forward current measurements showed only modest degradation, confirming trap-assisted recombination as the primary mechanism behind device deterioration. The combined results underscore the dominant role of trap-assisted recombination in leakage current enhancement and validate the SRH framework in describing carrier lifetime degradation due to mid-gap traps. Deviations at high fluence were attributed to interface effects and charge compensation mechanisms. These findings demonstrate the effectiveness of integrating atomic-scale simulations with device-level modeling to predict and interpret radiation effects in semiconductor detectors, providing a foundation for future radiation-hardened electronics design.

DREAM : A miniaturized spectrometer for protons and electrons measurement in space (#1273)

Arnaud Dufour[1], Robert Ecoffet[1], Julien Mekki[1], Alix Pierre-Louis[2], Jérôme Sadowy[2]

[1] CNES, Toulouse, France; [2] STEEL Electronique, Martres-Tolosane, France

This instrument has been funded by CNES.
CNES thanks STEEL and N7 Consulting for their technical contributions to this instrument.

Abstract

This paper describes a compact charged particles spectrometer called DREAM (French abbreviation of « Détecteur Radiation Energétique Adaptable et Miniaturisé »). It is a cubesat compatible radiation monitor, designed to measure protons (13 MeV – 200 MeV) and electrons (350 keV – 3 MeV) in space, essentially in the Earth's magnetic field. Built around silicon diode detectors co designed with STEEL Electronique and N7 Consulting, DREAM weighs around 400 g, fits within a 0.6 U volume (55 × 100 × 100 mm), and consumes less than 3W at 5 V.

The main goal of this instrument is to measure the dynamic behaviour of trapped charged particles flux in the magnetosphere, mainly disturbed by solar flares. It will then help to predict anormal fluxes that may damage satellites or humans in space. Experimental results show a good agreement between simulated and experimental spectra obtained at the UCL (62 MeV beam) and Partrec (184MeV beam) proton accelerators.

Qualification activities (radiation latch up tests, vibration, thermal cycling in vacuum, …) have been performed in 2025 and a detailed summary will be available in the paper. This instrument is already identified in several missions (mainly for the spaceweather), like the ESA S2P (Space Safety Programme) mission.

Abstract

Cadmium telluride (CdTe) is a leading room-temperature semiconductor for direct X- and γ-ray detection, but its performance is limited by bulk stoichiometric defects and interface-induced leakage current. Here, we report an integrated strategy combining vapor-pressure-controlled CdTe(Cl) crystal growth with noninvasive van der Waals (vdW) Au contacts to enhance bulk charge transport and interfacial charge control. Detector-grade CdTe(Cl) single crystals were grown by vertical gradient freeze using a Cd reservoir to stabilize Cd partial pressure and Cl doping to regulate compensation. This approach suppressed large Te inclusions below 5 μm, achieved ~60% infrared transmittance, and yielded high resistivity of 1.5×10^{10} Ω·cm, electron mobility of 1055 ± 88 $cm^2 V^{-1} s^{-1}$, and electron mobility–lifetime product of ~1.1×10^{-4} $cm^2 V^{-1}$. Planar Au/CdTe(Cl)/Au detectors showed clear ^{241}Am α-particle response. Mechanically transferred Au electrodes further formed vdW contacts that avoided atomic intermixing, preserved surface chemistry, reduced defect-related photoluminescence, and increased the Schottky barrier height from 0.78 to 0.83 eV. Consequently, vdW-contact CdTe detectors suppressed dark current and improved 59.5 keV γ ray energy resolution from 14.4% to 11.8%.

Alpha Particle Detection with sCMOS imager (#1770)

Makoto Sasano[1,3], Masateru Hayashi[1], Nobukazu Teranishi[2]

[1] Mitsubishi Electric Corporation, Advanced R&D center, Amagasaki, Japan; [2] Shizuoka University, Research Institute of Electronics, Hamamatsu, Japan; [3] Hirosaki University, Institute of Radiation Emergency Medicine, Hirosaki, Japan

Abstract

We investigated the alpha-particle response of a back-illuminated CMOS imager for radionuclide measurements in nuclear decommissioning. A GSENSE2020-BSI sensor with an approximately 10 μm-thick sensitive layer was used. To prevent alpha particles from reaching the circuit layer, measurements were performed with an 11 μm-thick aluminum foil and aluminized polymer sheets. The alpha-particle energy was varied by changing the number of sheets, and the resulting event images and deposited energy were analyzed. The expected deposited energy was calculated using Geant4, and single events were extracted using OpenCV-based image processing. The image intensity was calibrated to deposited energy using a ^{241}Am gamma-ray source.

Alpha-particle events appeared as spatially spread images. Under unsaturated conditions, the measured energy spectra agreed well with simulation, whereas ADC saturation caused underestimation at higher energies. Reliable energy information was obtained when the deposited energy was approximately 1.5 MeV or lower. The event area increased with deposited energy, following area is proportional to $E_{dep}^{1/3}$. These results demonstrate the potential of a back-illuminated CMOS imager for alpha-particle detection and nuclide identification.

Abstract

Silicon drift detectors (SDDs) are promising sensors for high-resolution X-ray spectroscopy because of their low anode capacitance, good timing capability, and scalability to large-area and multi-pixel detector systems. This work presents recent progress on single-pixel and array SDD technologies developed for space astronomy and synchrotron radiation applications. Single-pixel SDDs with sensitive areas from 15 to 85 mm² were designed and fabricated through optimization of the drift field, anode structure, leakage-current suppression, and dedicated semiconductor process. Low-noise front-end electronics, semiconductor packaging, and digital pulse-processing readout electronics were developed to support detector characterization and module integration. A 30 mm² single-pixel detector achieved an energy resolution of 135 eV at 5.9 keV at −40 °C, demonstrating the effectiveness of the device and readout design. Based on these developments, a first 19-pixel SDD module with a hexagonal 1+6+12 layout was fabricated, packaged, and tested for the Spectroscopy Focusing Array of the enhanced X-ray Timing and Polarimetry mission. The module integrates the SDD sensor, ceramic substrate package, low-noise front-end electronics, and high-density flexible readout interface. Low-temperature X-ray measurements showed that most

pixels satisfied the energy-resolution requirement, whereas the remaining pixels were mainly limited by increased dark current. The measured spectral response indicates the capability of the module to cover the required 0.5–10 keV energy range. These results validate the feasibility of the developed SDD technology for compact, low-noise, multi-pixel X-ray spectroscopy modules. The next stage will focus on the second-generation 19-pixel prototype and a 7-pixel SDD detector system for synchrotron radiation applications.

Abstract
Lead oxide (PbO) is a promising high-atomic-number photoconductor for direct-conversion x-ray detectors because of its high x-ray stopping power and low intrinsic electron–hole pair creation energy. A key challenge is depositing detector-grade thick PbO layers directly onto flat-panel imaging electronics while keeping the substrate temperature compatible with thin-film transistor and CMOS readout arrays. In conventional physical vapor deposition, limited adatom mobility at substrate temperatures below approximately 200 °C can promote porous, platelet-like polycrystalline PbO with reduced charge collection, temporal lag, and structural instability. In this work, oxygen-ion-assisted thermal evaporation was investigated as a low-temperature route for producing amorphous PbO photoconductors. Low-energy oxygen-ion bombardment supplied additional energy to the growing film surface without increasing the substrate temperature. The deposition conditions were optimized with respect to x-ray-to-charge conversion, evaluated using the average electron–hole pair creation energy, W±. Amorphous PbO layers with W± as low as approximately 7.5 eV/ehp and effective hole mobility on the order of 10^{-1} cm²/V·s at 10 V/μm were achieved. These results indicate that oxygen-ion-assisted deposition can produce amorphous PbO layers with detector-relevant charge generation and transport properties for direct-conversion flat-panel X-ray detectors.

Abstract

The General Antiparticle Spectrometer (GAPS) is an Antarctic long-duration balloon experiment designed to measure low-energy (< 0.25 GeV/n) cosmic antinuclei as signatures of dark matter. The distinctive GAPS particle identification technique relies on a tracker composed of > 1000 lithium-drifted silicon (Si(Li)) detectors – over 10 m^2 of silicon sensors – that both captures an incoming antinucleus into an exotic atom and measures the de-excitation X-ray and nuclear annihilation products. The GAPS program established the techniques necessary to produce large-area Si(Li) detectors, operable 150 ^oC above the liquid nitrogen temperatures typically required to achieve fine X-ray resolution, for an order of magnitude lower cost than previous commercially-available detectors. The distinctive detector geometry, together with custom polyimide passivation coatings that protect against humidity and organic contamination, has enabled remarkably robust operation: stable performance has now been

demonstrated after more than five years without requiring HV bias or low-temperature storage to prevent lithium redistribution. Detector segmentation, previously achieved through ultrasonic impact grinding, has now been demonstrated using a DISCO dicing saw, a less expensive alternative suitable for mass-production that opens new flexibility in detector and readout geometries. In this contribution, we review the features of such Si(Li) detector design and performance, and discuss the broader applications enabled by custom detector geometries.

Abstract

Neutron measurement technology is essential for the decommissioning of the Fukushima Daiichi Nuclear Power Plant and for monitoring special nuclear materials. In the former case in particular, high-dose gamma radiation is present, and there are significant constraints on size and weight. As a neutron detector suited to these environments, we focused on a neutron detector using silicon carbide (SiC) semiconductors, which offer higher radiation resistance than silicon semiconductors. In this study, we verified whether it is possible to distinguish and detect neutrons emitted from a ^{252}Cf neutron source from gamma rays in a high-dose gamma-ray background environment. The results showed that it is possible to distinguish between neutrons and gamma rays in a gamma-ray environment of up to 132 Gy/h.

Development of amorphous germanium blocking contact multi-electrode coaxial HPGe detectors for highcount-rate applications (#2621)

Siyuan Yu[1,2], Yang Tian[1,2], Li He[1,2], XiuXia Li[1,3], LiHui Han[1,2], MingXin Yang[1,2], Yuanjing Li[1,2], Yulan Li[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Key Laboratory of Particle & Radiation Imaging (Tsinghua University), Ministry of Education, Beijing, China; [3] Greater Bay Area National Center of Technology Innovation, Beijing, China

Abstract

High-purity germanium (HPGe) detectors are widely used in high-resolution gamma-ray spectroscopy and high-count-rate radiation measurements because of their excellent energy resolution and detection efficiency. Multi-electrode HPGe detectors can improve count-rate capability and provide local response information, but the calibration and summation of segmented-electrode signals remain challenging due to charge sharing, inter-electrode coupling, crosstalk and transient induced signals. In this work, a coaxial four-electrode HPGe prototype based on amorphous germanium blocking contacts was developed and tested. The detector consists of a small boron-implanted central P^+ electrode and three outer n-type segmented electrodes defined by amorphous germanium coating and aluminum metallization. The leakage current was below 10 pA at 200 V. Measurements with a ^{137}Cs source showed energy resolutions of 1.43–1.45 keV for the outer electrodes and 1.78 keV for the central electrode at 662 keV. Experimental and simulated four-channel waveforms were compared to evaluate induced responses in neighboring electrodes. Non-zero residual baselines observed in the experimental neighboring channels indicate coupling effects in the present frontend design. Simulated ^{137}Cs segment spectra and Ch1+Ch2 sum reconstruction further show that the central-electrode energy can serve as a reference for segment-energy calibration. These results demonstrate the feasibility of the amorphous-germanium-contact multi-electrode HPGe design and provide a basis for central-electrode-referenced correction and reliable segment-sum reconstruction in high-count-rate measurements.

A Novel Compton-Polarimeter in Telescope Configuration for X-Ray Energies up to 1 MeV (#2758)

Tobias Over-Winter[1,2], Anton Kononov[1], Thomas Krings[3], Wilko Middents[1,2], Uwe Spillmann[1], Günter Weber[1,4], Thomas Stöhlker[1,2]

[1] GSI Helmholtzzentrum für Schwerionenforschung GmbH, Darmstadt, Germany; [2] Friedrich-Schiller-Universität Jena, Institute of Optics and Quantum Electronics, Jena, Germany; [3] Forschungszentrum Jülich, Nuclear Physics Institute, Jülich, Germany; [4] Helmholtz-Institut Jena, Jena, Germany

Abstract

Compton polarimeters enable the detailed study of polarization sensitivity of fundamental radiative processes in the hard x-ray regime, i.e. for photon energies between 60 keV and 1 MeV. These detectors are based on double-sided segmented planar semiconductor crystals in which the recoil electron and the scattered photon of the Compton process are measured simultaneously. Within the SPARC collaboration (Stored Particles Atomic Physics Research Collaboration), a new Compton polarimeter in telescope configuration consisting of a Si(Li)- and a HPGe-detector has been developed, aiming for polarization experiments at particle accelerators and synchrotron facilities to analyze atomic or nuclear processes. A polarimeter consisting of only the first crystal, the Si(Li), was already operated in stand-alone mode in the energy range starting at 60 keV up to 250 keV. In a study of polarizazion-dependence of elastic scattering at the PETRAIII synchrotron facility of DESY, it proofed to be working well. Now the second crystal, the HPGe, was added to extend the accessible energy range up to the 1 MeV regime to widen the investigation of radiative processes. The main construction of the new detector system was performed at the detector laboratory of the Forschungszentrum Jülich, which is now relocating to the university of Cologne. We will report on the design of the novel Compton-polarimeter and first experimental applications.

Benefits from the latest Clover and Custom Desgined HPGe Detector Technologies (#3051)

Gabriela Ilie

Mirion Technologies, Product Management, Meriden, USA

Abstract

Mirion has been supplying sophisticated HPGe detectors and instrumentation which are used in cutting-edge materials analysis, fundamental nuclear physics research, and space studies to world's leading research institutes. The Clover [1] detector is one of Mirion unique product, recognized as an advanced gamma-ray detection system widely used in a variaty of different nuclear physics experiments. Clover detectors consist of four high-purity

germanium (HPGe) crystals, arranged in a compact cloverleaf-like configuration within a single cryostat. This unique geometry enhances its efficiency, enabling precise gamma-ray detection and energy resolution. The detectors design minimizes dead space, improving sensitivity to weak signals and increasing the likelihood of coincident gamma-ray detection for advanced spectroscopic studies. The Clover detectors versatility is augmented by its segmented configuration, which allows for effective background suppression and Doppler shift correction, making it invaluable for nuclear physics experiments and high-energy gamma-rays. Recent advancements in signal processing and digital electronics have further enhanced the performance of Clover detectors which continue to be a cornerstone in gamma-ray spectroscopy due to its high efficiency, excellent energy resolution, and timing. This presentation will provide an overview of various technologies for Mirion Clover detectors, highlighting the benefits of recent advancements like electrical cooling, an expanded energy dynamic range, and more.

An automated testing and characterization system for SiPM device arrays (#1148)

Stefano Riboldi[1,2], Agnese Giaz[2], Ciro Boiano[2], Sergio Brambilla[2], Franco Camera[1,2]

[1] *Universita degli Studi di Milano, Dipartimento di Fisica, Milano, Italy;* [2] *INFN, Milano, Milano, Italy*

Abstract
Large-area photodetectors in the form of silicon photomultiplier (SiPM) array detectors are becoming increasingly widespread in basic physics, medical, industrial, and security applications.
Various suitable devices are commercially available from companies such as Broadcom, Hamamatsu, and OnSemi. Alternatively, they can be constructed from individual SiPM devices.
After repeated use and initial testing of self-constructed devices, it is useful to characterize the electrical properties of each SiPM photodetector to determine the operating conditions of the array.
If the operational readout of the photodetector is based on a combination of theoretically available anode signals — for example, by short-circuiting all anode signals into a single readout channel — this verification procedure must be conducted using an independent test system.
This paper discusses the possible general structure of a fully automated test system, its implementation details, and its practical application by the user.
Through the implemented test procedures, the following can be determined:
Short circuits and open circuits on the printed circuit board housing the array under test
The individual I-V characteristic curves of the SiPM devices and the homogeneity of their operating parameters (e.g., breakdown voltage)
The operability, electro-optical conversion gain, response time, and saturation level of the signal of the individual SiPM devices through the injection of optical photons from a light-emitting diode (LED)
Depending on the tests performed, this test system can fully automatically determine the operational status of the SiPM device array within a time interval ranging from a few seconds to about ten minutes.

Abstract

Magnetron sputtering is a widely used technique for depositing both metallic and insulating thin films on diverse substrates. Its strength lies in the precise control it enables over film thickness and morphology, achievable through a detailed understanding of key physical processes such as gas ionization, plasma behavior, target sputtering, and film deposition. This level of control is particularly critical for high-energy physics detector technologies, where thin, uniform, and functional coatings such as those implemented in hybrid Resistive Plate Chambers are essential for optimizing detector performance, stability, and signal fidelity.

A promising pathway toward improving this control is the investigation of plasma-emitted light, which encodes valuable information about the composition, density, and dynamics of both working gas species and sputtered material. However, existing studies have largely relied on external optical observations or diagnostic techniques that perturb the plasma, limiting their effectiveness.

To address these challenges, we developed a high-precision, multi-parameter optical monitoring system capable of probing plasma emission directly within the sputtering chamber. The system samples light at key locations along the target-to-substrate trajectory with a timing resolution of up to 320 ps. Quartz optical fibers are integrated into the vacuum environment and coupled through a dedicated feedthrough to an external detection system. Signal acquisition is performed using Silicon Photomultipliers mounted on a custom-designed readout board.

This approach provides detailed insight into the temporal and spatial evolution of magnetron plasmas, enabling improved understanding of thin-film growth mechanisms. These results will contribute to the optimization of coating processes for next-generation detector systems in high-energy physics, enhancing their performance, robustness, and scalability.

This work is partially supported by the Erasmus+ programme.

Abstract

This paper reports on the recently deployed ISIS Digital Data Pipeline, which has facilitated an in-depth examination at the detector signals coming from the suite of Muon Spectrometers. Signal processing and event-mode analysis has been used to understand the afterpulsing characteristics of three types of photosensor; the HAMAMATSU R5505 1-inch PMT, the EMI-9954 2-inch PMT and S13360-1325PE HAMAMATSU SiPM. The R5505 was found to produce significant afterpulsing that can be identified via pulse shape discrimination due to their characteristically shorter fall time. This indicates impurity ionization, as the signals are not convolved with the scintillation response. The data pipeline has been tuned to suppress the afterpulses, producing data sets without this background contribution.

The authors would like to thank B. Leverington for his assistance with the SciFi geometry description as well as the SciFi team for the construction and operation of the SciFi detector.

Abstract

In high-energy physics detectors, Silicon photomultipliers (SiPMs) operated in mixed radiation fields show a dramatic increase in dark count rate (DCR), which affects detector performance. This work investigates whether the DCR of the SiPMs in the LHCb Scintillating Fibre Tracker can be used as an in-situ monitor of accumulated radiation exposure. The DCR at three delivered luminosities was recorded at the end of three consecutive yearly shutdowns and converted to area-normalized DCR. The results obtained were compared with radiation estimators obtained from particle-transport simulations using the latest detector geometry. The study focuses on total ionizing dose and 1 MeV neutron-equivalent fluence, which represent ionizing energy deposition and displacement-damage effects, respectively. The measured DCR was fitted as a linear function of each radiation estimator. Both estimators show a monotonic correlation with the measured DCR. The fitted slopes are approximately Gaussian after normalization, with relative dispersions of about 17 percent when all tracking stations are combined and about 13 percent when the stations are treated separately. This reduction indicates that part of the response spread is associated with station-dependent effects rather than with channel-to-channel variations only. The two radiation estimators cannot be uniquely separated with the present dataset. The results therefore support an empirical parameterization of DCR as a proxy for the considered radiation estimators, rather than a unique identification of the underlying damage mechanism. With appropriate station-wise calibration, this approach could provide a way to estimate the accumulated total ionizing dose or 1 MeV neutron equivalent fluence from post-shutdown DCR measurements.

Radiation-Hardened CMOS-SPAD Design for Stable Geiger-Mode Operation (#2314)

Doo-Hee Son, Doyoon Eom, Myung-Jae Lee

Yonsei University, Department of Electrical and Electronic Engineering, Seoul, South Korea

Manuscript received May 12, 2025. This work was supported by the Yonsei University Research Fund of 2025 (2025-22-0433), the Institute of Information & Communications Technology Planning & Evaluation (IITP) grant funded by the Ministry of Science and ICT (MSIT) (RS-2025-02218723), and the National Research Council of Science & Technology (NST) grant by the Korea government (MSIT) (GTL25011-000).

Abstract

Single-photon avalanche diodes (SPADs) are advanced semiconductor photodetectors that operate in Geiger mode, offering single-photon sensitivity and sub-nanosecond timing resolution for biomedical and space applications where robust radiation hardness is essential. In these environments, prolonged gamma-ray irradiation causes total ionizing dose effects, in which holes generated in silicon dioxide become trapped near the silicon/silicon dioxide interface, forming positive oxide-trapped charges and promoting interface trap formation. The progressive accumulation of these charges distorts the local electric field distribution near the guard ring periphery, causing field crowding that can promote premature edge breakdown and compromise stable Geiger-mode operation. This work employs technology computer-aided design (TCAD) simulations using the Sentaurus tool to compare a conventional virtual guard ring structure with a proposed physical guard ring realized by a deep p-well, available in complementary metal-oxide-semiconductor (CMOS) processes. Simulation results demonstrate that the virtual guard ring exhibits persistent edge field crowding exceeding the device junction field across all irradiation conditions, whereas the physical guard ring maintains its edge field below the junction level over a wide irradiation range. These results confirm that the deep p-well-based physical guard ring effectively reduces the risk of premature edge breakdown, offering a promising radiation-tolerant design strategy for CMOS SPADs.

This project has received funding from the French National Research Agency under grant No. **ANR-19-CE19-0009-01** and **ANR-24-CE45-7518**.

Abstract
The ClearMind project aims to improve Time-of-Flight Positron Emission Tomography by developing detection modules with a Coincidence Time Resolution of 100 ps FWHM or better. This performance is achieved through the simultaneous detection of Cherenkov and scintillation photons within the PWO crystal window of a Micro-Channel-Plate PhotoMultiplicator Tube read out by transmission lines. The first prototype, assembled by Photek (UK), demonstrated the feasibility of such technology but has a suboptimal time resolution of 370 ps

(FWHM) when detecting 511 keV gamma photons. To address these challenges, we are improving the photocathode design, with the next prototype to be assembled by Incom (USA). As a first step, we evaluated the performance of standard Incom's High-Resolution Photon Detector (HRPPD) MCP-PMT with a capacitive readout. Tests were conducted using both a pulsed laser in single-photon mode and a ^{22}Na radioactive source. The HRPPD's capacitive readout system, which is compatible with the ClearMind's transmission line design, has achieved a single-photon Transit Time Spread as low as 50 ps (FWHM) for high-gain events and a spatial resolution of about 1 mm (FWHM). Photocathode deposition on PWO trials at Incom remains stable over time and confirms its feasibility. Through realistic simulations combined with machine learning-based reconstruction, we investigate the factors limiting the time resolution in ClearMind technology and demonstrate that a time resolution below 100 ps is achievable for large-size PWO modules under certain conditions.

Abstract

Fast-timing γ-ray spectroscopy based on $LaBr_3(Ce)$ scintillators coupled to photomultiplier tubes (PMT) is a well-established technique for measuring lifetimes of excited nuclear states in the picosecond-to-nanosecond range. In this work, we present a comparative characterization of different $LaBr_3(Ce)$ crystals of various sizes and geometries coupled to several Hamamatsu PMT models: R9779 (H10570), R13089 (H13719-Y006 and H13719-Y007), and R13408-Y006. The study focuses on timing performance, linearity, and energy resolution using digital signal processing. While the discontinued R9779 remains a benchmark for timing performance, the newer PMT models exhibit good linearity, comparable energy resolution for a given crystal, and competitive coincidence time resolution.

Abstract

The Silicon Vertex Tracker (SVT) of the EPIC detector adopts a serial powering scheme to distribute electrical power to Monolithic Active Pixel Sensors (MAPS) that are mounted on outer barrels, and electron and hadron end caps. Serial powering is an advantageous powering scheme because it reduces the mass required by electrical services. This is important in order to achieve the target material budget in staves and disks, which can be as low as 0.25% X/X_0.

The Shunt Low Drop Out (SLDO) voltage regulator is key to the serial powering scheme. Four SLDOs are connected to each MAPS to supply its 4 different power domains. This forms a coherent electrical unit that is repeated in a serial chain. A constant current is distributed through the SLDOs in this serial chain.

The SLDO is a bespoke circuit design. It supplies up to ~1.0 A of output current with an output voltage in range 1.1 V to 1.4 V. The chip was designed in a 110 nm process.

A series of SLDO chips were irradiated at the X-ray Irradiation Facility at Daresbury Laboratory (UK). X-rays were produced via Bremsstrahlung from electrons hitting a Tungsten target. The irradiation campaign studied the circuit response against the Total Ionising Dose (TID) requirements of the EPIC detector. The target TID for EPIC-SVT is estimated to be of the order of 200 krad(SiO_2), integrated over a period of 10 years of operations. This estimate is based on a worst case scenario where a beam of 100 GeV electrons collides with a beam of 275 GeV protons for a period of 6 months per year.

TID irradiations characterised the performance of the SLDO chip for different settings of input voltage, output loads, and different temperatures. Irradiations were carried out at different dose rates, as high as ~100 krad(SiO_2)/min. Annealing was monitored after irradiation.

Characterization of Single-Event Upsets in a 90 nm Commercial Off-the-shelf SRAM caused by Low-Energy Protons (#1482)

Shintaro Ishihara, Yukimune Uchida, Sho Toyama, Wataru Kada, Shigeo Matsuyama

The authors gratefully acknowledge N. Shibanuma for constructing the single-event effect irradiation field used in this study.

Abstract

In contradistinction to conventionally manufactured radiation-hardened devices, which demonstrate radiation tolerance and reliability, commercial off-the-shelf (COTS) devices may exhibit vulnerability to single-event effects (SEEs) resulting from direct ionization in environments dominated by protons, such as in low earth orbit (LEO). The issue of limited cross-section data availability for such protons with low energies has been addressed by a dedicated SEE, particularly single-event upset (SEU), evaluation field based on a 1MV tandem accelerator. In the present study, low-energy proton beams with an energy range of between 0.40 and 1.65 MeV have been irradiated to 90-nm COTS SRAM. The proton-induced SEU cross-sections were found to be several orders of magnitude lower than the predicted values through the Weibull plot derived from conventional data. Moreover, an approximate tenfold enhancement in SEU cross-section was observed at the energy of 0.447 MeV, coinciding with a roughly twofold increase in accumulated fluence. The findings present novel experimental insights into the energy- and ion-species- dependent mechanisms underpinning SEU occurrence in COTS.

Abstract

Traditional radioactive source testing involves health risks, regulatory limitations, and operational inconvenience. To address these issues, this paper presents a nuclear-like signal generator capable of reproducing the waveform, amplitude, and timing characteristics of real nuclear radiation signals. The proposed system is implemented on a Xilinx K7 FPGA and supports parameter configuration through a touch screen, USB, Ethernet, or host computer software. In the waveform-generation module, photon emission timing is modeled according to scintillator light yield and decay time, while photoelectric conversion jitter and Gaussian pulse responses are introduced to synthesize realistic macroscopic waveforms. In the amplitude-generation module, a cumulative distribution function threshold table derived from measured energy spectra is used to reproduce statistical energy distributions. In the timing module, event occurrence is modeled as a Poisson process with exponentially distributed intervals. The system supports multiple radioactive sources and scintillator materials, including Na, Cs, LYSO, NaI, CsI, and BGO, with independent dual-channel output capability.

Abstract

Ensuring reliable RF operation in radiation-prone is critical for wireless monitoring systems in nuclear and space applications. This work presents a radiation-hardened-by-design (RHBD) voltage-controlled oscillator (VCO) implemented in a 28 nm Fully-Depleted Silicon-On-Insulator (FDSOI) process and experimentally evaluated under total ionizing dose (TID) conditions. The proposed RHBD VCO is compared with a conventional design up to 370 kGy(Si) using a Cobalt-60 gamma irradiation source at KAERI. Measurement results demonstrate that the RHBD VCO significantly improves frequency stability, achieving up to 57% reduction in frequency drift compared to the conventional counterpart. In addition, enhanced output power stability and reduced supply current variation are observed under irradiation. The results highlight the combined benefits of FDSOI technology and circuit-level hardening techniques, demonstrating a robust solution for radiation-tolerant RF circuit design.

Abstract

R-2R ladder converters in nuclear instrumentation are vulnerable to total ionizing dose (TID) because threshold-voltage shifts in NMOS switching transistors perturb on-resistance ratios that govern ladder accuracy. Preliminary irradiation measurements motivate a circuit-level solution: a modest on-resistance increase already drives worst DNL beyond 1 LSB. The proposed converter in 0.18 μm BCD employs a two-layer hardening strategy. The first layer uses a switch-compensated R-2R topology where all resistors share the same R+Ron unit, canceling Ron[if gte msEquation 12]><m:oMath><m:sSub><m:sSubPr><m:ctrlPr></m:ctrlPr></m:sSubPr><m:e><span lang=EN-US style='font-size:10.0pt; font-family:"Cambria Math",serif;mso-fareast-font-family:"맑은 고딕";mso-fareast-theme-font: minor-fareast;mso-bidi-font-family:"Times New Roman";mso-ansi-language:EN-US; mso-fareast-language:EN-US;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>R</m:r></m:e><m:sub><span lang=EN-US style='font-size:10.0pt;font-family:"Cambria Math",serif; mso-fareast-font-family:"맑은 고딕";mso-fareast-theme-font:minor-fareast; mso-bidi-font-family:"Times New Roman";mso-ansi-language:EN-US;mso-fareast-language: EN-US;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>on</m:r></m:sub></m:sSub></m:oMath><![endif] in the transfer function. The second layer preserves this cancellation through branch-local diode-replica biasing: a per-branch source-tracking loop and a scaled NMOS replica enforce uniform VGS,Ref on every dummy switch, with a constant-transconductance reference anchoring gm,rep to a poly-silicon ratio. Simulations across multiplicities 5–50 at 27 ℃ and 200 ℃ show the proposed converter achieves the 1 LSB target at multiplicity 15 vs. 40 for the conventional reference (2.7× area reduction). At multiplicity 20, worst DNL is 0.564 LSB at 200 ℃ vs. 2.471 LSB, with ~4.4× major-carry DNL improvement.

Abstract

The next generation of imaging atmospheric Cherenkov telescope (IACT) cameras is transitioning to silicon photomultipliers (SiPMs) due to their stability, robustness, and superior sensitivity compared to PMTs. Specifically, we are developing an ASIC for the advanced SiPM camera (AdvCam). This ASIC, designated as PRESSEC (Preamplifier Readout Electronics for Summing SiPMs Enhanced Circuit), is implemented in 65 nm CMOS technology. The PRESSEC utilizes a 32-input scheme for large-area sensor readout. Its primary function is to generate analog outputs by summing signals from four sensors into a single channel, effectively reducing the total output count to eight channels. The main functionality of this ASIC is housed in the energy path, which integrates a single-ended-to-differential converter and a pole-zero cancellation circuit. This structure is instrumental in reducing the pulse's Full Width at Half Maximum (FWHM) to 3 to 5 ns, thereby mitigating pileup effects in high activity environments. Simultaneously, these signals feed a trigger system for rapid event identification via a fast comparator. Additionally, a dedicated Night-Sky Background (NSB) monitoring circuit is included to measure ambient noise from sources like moonlight, employing a slow integrator with adjustable high-value pseudo-resistors to achieve integration time constants in the order of the milliseconds. Rigorous performance benchmarks, validated using Hamamatsu and FBK SiPMs, show a signal-to-noise ratio of at least 5, a dynamic range of 300 photons, and a linearity error below 3% for both energy and NSB paths, while presenting a power consumption of approximately 10 mW per input channel.

Feasibility studies on readout topologies for a MHz-framerate continuous wave-mode X-ray detector in 45nm SOI CMOS technology

(#2069)

Pradeep Kalavakuru, Karsten Hansen, Stefano Maffessanti, Christian Reckleben, Inge Diehl, Uttal Ghosh

DESY - Deutsches Elektronensynchrotron, FE, Hamburg, Germany

The authors would like to thank Eric Wüstenhagen for technical discussions.

Abstract

This work presents a concept and feasibility study of a data readout circuit topology for a pixel matrix with in-pixel digitization, enabling continuous wave-mode X-ray detectors operating at MHz frame rates. The key components comprise dedicated high-speed column and row serializers based on custom-designed flip-flops with an optimized timing scheme. The readout topology is tailored to interface with silicon photonics electronic-photonic integrated circuits, enabling high-bandwidth and scalable data transmission. For a 64×64-pixel configuration, simulations confirm achievable frame rates of up to 4.5 MHz with the proposed architecture. At 1.125 MHz, the total readout circuitry consumes 100 µW per pixel at a supply voltage of 1 V. Design trade-offs in area, speed, mechanical integration and power consumption are analyzed, demonstrating the modularity of the architecture for high-frame-rate detector systems.

Abstract

The experimental characterization of MAGIC (Multichannel Analog Gamma- ray detection Integrated Circuit) is here presented. This ASIC is designed in CMOS 110 nm technology and it is intended to readout the current signals coming from SiPMs coupled with monolithic scintillators that are used in medical imaging applications. The circuit is divided into three main sections: an energy path that provides a differential voltage proportional to the energy of the gamma photon, a timing path that gives information about the time of arrival of the photon, and a validation path for event discrimination. For the experimental characterization two PCBs, a mainboard and a carrier, have been designed. In this testing phase all the functionalities have been validated and the key performance of the ASIC have been characterized, in particular the power dissipation (5 mW/channel), the linearity of the energy chain to demonstrate the direct proportionality between the measured charge and the one generated by photon interaction, and the time jitter which affects the propagation delay through the timing path. The results are within the specifications and confirmed by simulations: the linearity error is below 1% and the time jitter is below 20 ps. Such a low value enables its use also in TOF-PET applications.

A Modular Warm Time-Division MultiplexedReadout Platform for SQUID Applications (#2181)

Benjamin A. Reese, Gunther Haller, Shawn W. Henderson, Leonid Sapozhnikov, Zeeshan Ahmed

SLAC National Accelerator Laboratory, Menlo Park, USA

Abstract

Many low-temperature detector experiments require a maintainable replacement for the warm Multi-Channel Electronics used for time-division multiplexed (TDM) readout of superconducting quantum interference device (SQUID) amplifiers. This work presents a modular warm TDM readout platform whose architecture replaces the MCE backplane model with a common FPGA carrier, pluggable analog front ends, simple 12 V board power, and commodity network interfaces. The carrier hosts 16 two-channel fast DACs for 32 waveform outputs and an eight-channel 125 MSPS ADC. In a column-readout configuration, the fast DACs provide SQUID Series Array (SSA) feedback, Stage 1 SQUID (SQ1) bias, and SQ1 feedback for eight columns, while the column front end provides SSA bias, transition-edge sensor (TES) bias, and amplification of SSA return signals. In a row-select configuration, the same carrier drives 32 fully differential analog outputs that support two-level row and chip selection. Shared firmware provides timing distribution, configuration, data streaming, and communications, while role-specific firmware implements row-select sequencing or column ADC processing with SQUID flux-locked-loop feedback. Multiple carriers with attached front ends form scalable readout groups. One carrier in each group is configured as the coordinator and provides the SFP+ 10 Gb/s Ethernet interface to the back-end DAQ and configuration system. The platform has demonstrated 1 MHz row rates with 80 active rows.

This work was supported in part by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231

Abstract

This work presents the design and preliminary experimental validation of an ASIC developed as a test vehicle toward a comprehensive cryo-CMOS process development kit (PDK) for a commercially available 28\,nm bulk CMOS process. A CMOS device array utilizing a row-column addressing architecture for rapid characterization of nearly 2000 NMOS and PMOS devices with different geometries and threshold-voltage flavors, has been fabricated and experimentally validated. The complete transistor array can be evaluated using only 16 external wires, making the platform easily adaptable in a dilution fridge for deep-cryo testing. Separate gate-bias control of unselected devices is implemented to minimize leakage current, while a 4-wire sensing scheme improves measurement accuracy. The large-scale cryogenic characterization enabled by this approach represents an important step toward the development of accurate cryo-CMOS PDKs and reliable IC design methodologies for high-energy physics (HEP), quantum computing, and other cryogenic applications in deeply scaled CMOS technologies.

The fabricated die comprises 13 subarrays covering 10 device flavors, including NMOS and PMOS transistors with high-, regular-, low-, and ultra-low-threshold voltage options, native as well as deep N-well NMOS devices. In addition, duplicated regular-Vt arrays are included to evaluate intra-chip process variations. An integrated scan chain selects one transistor at a time, with all remaining device gates independently biased to suppress leakage during measurement. Preliminary results confirm correct scan-chain operation and successful device selection, with measured I_d - V_{gs} characteristics showing expected current scaling across different device geometries. Comprehensive cryogenic characterization from 77K down to mK temperatures is planned as the next step toward completing the cryo-CMOS PDK.

Intermediate-Dose Close-In Phase-Noise Instability in a 55-nm CMOS PLL Irradiated to 100 Mrad(Si) (#2358)

Peng Zheng, Yiming Wu, Chao Lv, Wanchang Wang, Xueye Hu, Jinhong Wang

University of Science and Technology of China, Department of Physics, Hefei, China

Abstract

This work presents an in-situ total ionizing dose (TID) characterization of a 2.56 GHz charge-pump phase-locked loop (PLL) implemented in a commercial 55 nm CMOS process for high-energy physics front-end clocking applications. The chip was irradiated with X-rays up to 100 Mrad(Si), while phase noise, integrated jitter, supply current, and lock status were monitored throughout dose accumulation. Although the endpoint degradation is limited, with the RMS jitter integrated from 1 kHz to 10 MHz increasing from approximately 550 fs to 700 fs after 100 Mrad(Si), the in-situ measurements reveal a more critical intermediate-dose effect. Around 10 Mrad(Si), the

PLL exhibits strong close-in phase-noise instability, mainly from 1 kHz to 100 kHz offset frequency. Standalone VCO measurements show no similar fluctuation, indicating that the observed behavior is unlikely to originate from the LC-VCO and is more consistent with radiation-enhanced low-frequency noise in the loop-control path. These results show that final-dose measurements alone may underestimate the worst-case phase-noise degradation of PLLs under TID exposure.

A Low-Noise Multi-Channel Readout ASIC for High-Purity Germanium Detectors (#2413)

Li He[1,2], Yulan Li[1,2], Yang Tian[1,2], Yuanjing Li[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Ministry of Education, Key Laboratory of Particle & Radiation Imaging (Tsinghua University), Beijing, China

Abstract

Multi-electrode High-Purity Germanium (HPGe) detectors are promising for high-count-rate gamma spectroscopy, but traditional JFET readouts suffer from excessive power (~200 mW per channel, >3.2 W for 16 channels), bulky volume, and severe outgassing. This paper presents a low-noise, high-integration readout ASIC implemented in TSMC 0.18μm CMOS, featuring 18 P+ and 18 N+ channels. Each channel consists of a continuous-feedback charge-sensitive amplifier (CSA), a CR-RC shaper employing ICON cells (1 GΩ equivalent resistance) for large time constants, and a class-AB buffer. A PMOS-input folded-cascode topology is utilized for optimal noise performance. Room-temperature measurements demonstrate a total power consumption of 594 mW (180 mA @ 3.3 V) for all 36 channels, presenting a significant advantage over JFET solutions. The ASIC achieves a gain of 11.3 mV/fC, an integral non-linearity (INL) < 1% over 40 keV to 1.5 MeV, and a rise time of ~65 ns. With a 10 μs shaping time, the equivalent noise charge (ENC) is approximately 58 e^- at zero input capacitance. Future work will focus on cryogenic evaluation with HPGe detectors and noise slope characterization.

A precision bandgap reference with improved noise performance for spectroscopy ASICs in 180 nm CMOS technology (#2577)

Yinhe Zhu[1], Filippo Mele[1,2], Giuseppe Bertuccio[1,3]

[1] Politecnico di Milano, Department of Electronics, Information and Bioengineering, Milano, Italy; [2] Istituto Nazionale di Astrofisica (INAF), Istituto di Astrofisica e Planetologia Spaziali (IAPS), Roma, Italy; [3] Istituto Nazionale di Fisica Nucleare (INFN), Sezione di Milano, MIlano, Italy

Abstract

We present the design of a low-noise and low-offset bandgap reference (BGR) circuit intended for front-end readout ASICs for semiconductor radiation detectors (SRDs). To suppress low-frequency noise and reduce process-induced dispersion of the reference voltage and proportional-to-absolute-temperature (PTAT) current, a voltage-domain BGR architecture employing local positive feedback is designed [1]. The circuit technique suppresses the dominant noise and offset contributions originating from the error amplifier. Compared to a conventional topology operating at the same power consumption of 50 µW, the proposed circuit achieves a tenfold reduction in low-frequency noise. The circuit is implemented in a 180 nm deep N-well CMOS process from amsOSRAM and operates from a 1.8 V supply voltage, occupying a total area of 0.024 mm^2. Post-layout simulation results show a tenfold reduction in the 1/f noise, a voltage power spectral density of 200 nV/√Hz from 100 Hz up to 1 MHz and a DC accuracy of 0.06 %. In addition, the proposed BGR achieves a temperature coefficient of 30 ppm/°C over the temperature range from -40 °C to 125 °C.

Photon Counting with FPGA Gigabit Transceivers: A Proof-of-Concept SiPM Readout for TOF-PET (#2884)

Tarun Prakash, Joshua W. Cates, Woon-Seng Choong, Marcos Turqueti

Lawrence Berkeley National Laboratory, Berkeley, USA

This work was supported in part by NIH Research under Grant R01EB033402

Abstract

Achieving 100ps FWHM coincidence time resolution (CTR) in time-of-flight positron emission tomography (TOF-PET) is benefited by electronics that can resolve individual scintillation photons with high temporal precision. We report a proof-of-concept readout in which silicon photomultiplier (SiPM) single-photon pulses are discriminated by a high-speed comparator and digitized directly by GTY transceivers of a Xilinx Virtex UltraScale XCVU095 FPGA (VCU1287 board) at 16Gbps, encoding photon arrival times as bit positions with 62.5ps resolution. Signal integrity analysis showed that an initial LVDS comparator produced common-mode voltage and differential swing below GTY receiver specifications; switching to a CML comparator substantially reduced bit errors. Room-temperature SiPM dark count bitstreams were captured with a random FPGA clock trigger and post-processed to produce a finger plot showing 1-, 2-, and 3-photoelectron peaks, providing a preliminary validation of the bitstream-based photon-counting concept. These results support the feasibility of FPGA gigabit transceivers as scalable digitizers for single-photon pulse streams in next-generation TOF-PET detector modules.

This work is supported by the IGNITE project (INFN Ground-up INITiative-on micro- Electronics developments) of the Italian National Institute for Nuclear Physics (INFN), and PNRR(National Recovery and Resilience Plan) Etic (Einstein Telescope Infrastructure Consortium) project.

Abstract

This work presents a Phase-Locked Loop (PLL) integrated in 28 nm Bulk CMOS HPC+ technology, developed within the INFN Ground-up iNITiative for Electronics developments (IGNITE) project. It is designed to generate low-jitter clock signals at 40 MHz for high-time-resolution charge measurement, and at 640 MHz for high-speed data serialization.

In High Energy Physics, mixed-signal circuits must withstand severe radiation damage, both cumulative, in the form of Total Ionizing Dose (TID) up to 1 GRad, and event-driven, in the form of Single Event Effects (SEEs) induced by particles with Linear Energy Transfer (LET) values up to 60 MeV·cm²/mg. To address these effects, the PLL was implemented using radiation- hardened-by-design-oriented techniques. Experimental validation in time and frequency domains confirmed cycle-to-cycle jitter values of 11.437 ps RMS and 1.95 ps RMS for the 40 MHz and 640 MHz outputs, respectively. Power consumption is 8.4 mA from a 900 mV supply. The total active area is 0.0174 mm².

Machine-Protection System for the PIP-II Linear Accelerator: Architecture and Data Processing Schemes (#1193)

Jinyuan Wu, Arden Waner, Jonathan Eisch, Mark Austin

Fermi National Accelerator Laboratory, Batavia, USA

This manuscript has been authored by Fermi Forward Discovery Group, LLC under Contract No. 89243024CSC000002 with the U.S. Department of Energy, Office of Science, Office of High Energy Physics.

Abstract

PIP-II at Fermilab features a brand-new, 800 MeV leading-edge Linear Accelerator (Linac) that will enable the Fermilab complex to deliver more than a megawatt of beam power to the Long Base-line Neutrino Facility (LBNF), requiring a robust Machine Protection System (MPS) to prevent beam-induced damage to delicate cryomodules and vacuum components. Signals in various accelerator components, in both analog and digital format, are collected and processed to assest the operating conditions of the accelerator. In the situation a potential damage is foreseen, the beam permit signal will be drop. A critical element of this system is the fast Analog Machine Protection System, a high-bandwidth platform designed for real-time beam loss monitoring. The system utilizes a modular, FPGA-based architecture to digitize signals from beam-sensing devices, such as AC Current Transformers (ACCTs), non-invasive Ring Pickups (RPUs) and beam scrapers. To eliminate both high frequency as well as 60 Hz noise that might be picked up in the industrial environment, data processing schemes beyond regular digital filtering are planned and implemented.

Comparison of discrete non-gated charge-to-time converters for SPECT application (#1264)

Pauline Lafoux, Nicolas Chevillon, Christian Fuchs, Tom Robert, Virgile Bekaert, Frederic Boisson

Université de Strasbourg, CNRS, Institut Pluridisciplinaire Hubert Curien UMR7178, Strasbourg, France

Abstract

In the context of tomographic imaging, a simple and modular readout combines non-gated charge-to-time converters (QTC), composed of few discrete analog components, and time-to-digital converters implemented in FPGA. The choice of discrete QTC's architecture depends on a compromise between number of components per channel, charge RMS resolution and dead time. Because temperature drift can lead to high measurement error and temperature compensation circuit costs lot of surface per channel, another key parameter to consider is the QTC's

response stability to variation of temperature. This study compares three continuous-reset QTC topologies, named after their feedback circuit (RC, diode, and MOSFET). Each circuit is implemented with discrete components and tested in a dynamic range from 2 pC to 35 pC, for a Single-Photon Emission Computed Tomography (SPECT) application. Unlike previous work, we compare them on conventional figures of merit and also evaluate their TOT-Q characteristics stability for temperature variation over 20 °C. Experimental results show that the RC QTC reduces dead time by a factor of 2 compared to linear designs, while the diode-QTC and MOSFET QTC achieve sub-0.1pC charge RMS resolution. However, the MOSFET QTC exhibits a 1.2 %/°C relative error due to temperature-dependent drain current. And diode-QTC requires a temperature compensation circuit to remain stable as RC-QTC (<0.2 %/°C).

150 Gbps data transfer Bay simulating Agata detector Readout (#1274)

Nabil Karkour, Xavier LAfay

Université Paris–Saclay, CNRS/IN2P3, IJCLab 91405 Orsay, France, Electronic, Orsay, France

The authors acknowledge the support of the AGATA collaboration in the work described in this publication and who helped us financially to achieve our goals. The 150 Gbps Bay development have been financed by CNRS, IN2P3, France. Special thanks to Gustav Vinther-Jørgensen and to Andrea Triossi who supported the STARE Proof Of Concept. . Many thanks would like to thank the IJCLAB Orsay AGATA team to make this project successful.

Abstract
The Advanced Gamma Tracking Array (AGATA) spectrometer consists of 180 high-purity germanium detectors, each segmented into 38 segments. The trigger rate of each detector can go up to 50 kHz. The data transfer rate per detector ranges from 5 to 8 Gbps. Moreover, continuous monitoring data is sent over the network using another link, resulting in a total outgoing data rate of approximately 18 Gbps using User Datagram Protocol (UDP). The total transfer rate of 180 detectors can go up to 3.2 Tbps during a period of 1 to 3 weeks of continuous operation. The bay is designed in parallel with the Phase 2 front-end electronics development and production so that the complex readout system from these electronics to the computer farm is validated. The 10 Gbps UDP transfer is not totally secure; at such a data readout speed, the computer receiver uses most of its processing and memory capacities. The bay simulates the Phase 2 electronics data readout of more than 12 AGATA detectors using the Serial Transfer and Readout over Ethernet (STARE) modules. The bay is designed to validate the complex readout system from the Phase 2 electronics to the computer farm and to test the overall data acquisition system reliability. Data quality is mandatory for the scientific results, and any data loss could degrade the physics case and the system efficiency. This article will show how the bay simulates the multiple-source data readout to the computer farm at over 100 Gbps.

Abstract

CPRE64 is a 64ch readout ASIC specifically optimized for three-dimensional position-sensitive Cadmium–Zinc–Telluride (CZT) detectors, developed from the CPRE32 . The chip is capable of reading both cathode and anode signals, allowing it to match pixelated, virtual Frisch-grid CZT or silicon detectors. Each channel integrates a low-noise charge-sensitive amplifier (CSA), high-order shaper, peak detect-and-hold (PDH) circuit for energy measurement, and sample-and-hold circuit for timing measurement. Power consumption is below 5 mW per channel. The ASIC incorporates a layout designed for SEE hardening, resulting in a die area of 7.10 mm × 12.44 mm^2. The chip layout features pins on three sides for permitting expansion to 128 channels . Experimental results show: when a CZT sensor connected and biased, the electronic resolution better than 150 e^-(rms) for anode channel, better than 250 e^-(rms) for cathode channel. The readout channel exhibits linearity with ≤1.5% integral nonlinearity, with a maximum dynamic range reaching 350 fC. Spectral measurements applying a simple depth correction demonstrated a single-pixel resolution of 0.78%(FWHM) at 662 keV.

This work was supported by NASA under Contract 80GSFC21C0059.

Abstract

We have developed an application-specific integrated circuit (ASIC) to read out high-purity germanium (HPGe) strip detectors, which will be used as the front-end readout for the HPGe double-sided strip detectors flown aboard the Compton Spectrometer and Imager NASA Small Explorer mission. Here we present an overview of the ASIC, focusing on its fast timing capabilities. The ASIC has 32 channels, each of which contains two shaping circuits to allow for high-resolution measurements of both the charge collected, which is proportional to the energy deposited, and the time of collection. By taking the difference between the charge carrier arrival times on each side of the detector, we can determine the interaction depth in the detector. We evaluated the performance of the ASICs using engineering models of the COSI flight boards. To assess the timing performance in particular, we used a dual-channel function generator to pulse two ASICs, with one channel delayed from the other by various amounts. We also present preliminary measurements of the ASIC timing performance on a COSI-like detector using a fan beam collimator placed to illuminate discrete depths.

Abstract

Advanced X-ray sources such as synchrotrons and Free Electron Lasers (FELs) enable ultrafast time-resolved experiments, requiring acquisition systems with event-by-event timing and spatial resolution. Cross Delay-Line (CDL) detectors are well suited for simultaneous time–space encoding via time-to-space conversion. Standard high-performance architectures rely on Application-Specific Integrated Circuit (ASIC)-based Time-to-Digital Converters (TDCs) or Time-to-Amplitude Converters (TACs), followed by Field-Programmable Gate Array (FPGA) processing, but lack reconfigurability. We present a high-performance, fully FPGA-based reconfigurable acquisition system implementing both the TDC and real-time 3D (x, y, t) reconstruction in programmable logic, eliminating ASIC dependence while maintaining state-of-the-art performance and enabling full adaptability to experimental conditions. The system employs a two-FPGA architecture, with a 8-channel TDC and a dedicated reconstruction unit. The TDC achieves 12 ps rms timing precision, 9.6 ns dead time, and 4 ps integral non-linearity, corresponding to 24 and 27 µm spatial resolution on the CDL for the x and the y coordinates, respectively. This approach enables scalable, high-throughput, fully digital, and reconfigurable time-resolved imaging with spatial and temporal resolution comparable to state-of-the-art ASIC-based solutions.

High-performance preamplifier for spectroscopy systems based on High-Purity Germanium detectors (#1999)

Fernando Ojeda, **Fernando Ojeda**, Brian Nelson, Brian Nelson

AMETEK ORTEC, Oak Ridge, USA

The authors wish to acknowledge the valuable contributions to this work from the Engineering, Production, and Detector Test teams.

Abstract

Preamplifiers play a primary role in the resolution, linearity, and sensitivity of ionizing radiation spectrometers, converting the small charges collected by photo detectors into usable voltage signals that are further amplified, digitized, and processed to obtain the intended spectra. Additionally, the accuracy and thermal stability of such charge-to-voltage conversion must be assured to keep a constant performance over time and across different detectors, wiring configurations, and radiation scenarios. This article presents electronic simulations and the first laboratory results showing recent improvements in a new preamplifier designed for High-Purity Germanium spectroscopy systems, in terms of dynamic response, noise, linearity, thermal stability, symmetry, tolerance to reactive loads, piling-up, saturation recovery, and power consumption. The impact of these improvements is also discussed.

Abstract

Correlating molecular neuroimaging with behavior in preclinical models requires acquisitions in awake and freely moving animals, whereas most current positron emission tomography procedures are still performed under anesthesia.

The MAPSSIC project addresses this limitation with an implantable intracerebral probe based on monolithic active pixel sensors (MAPS) for direct positron detection in targeted brain structures of awake, freely moving rats, thereby avoiding the pharmacological bias of anesthesia. Following sensor characterization and simulation studies previously reported, this contribution presents the transition to a fully wireless system. The acquisition chain combines four IMIC2 sensor chips, a STM32L4 microcontroller, 1 Gbit on-board flash memory, and a bidirectional 2.4 GHz radio link to a Raspberry Pi ground station. The complete software stack is implemented in Rust with the Embassy asynchronous framework, providing memory safety and concurrent peripheral management without dynamic allocation. Planned validation with ^{18}F, ^{11}C phantoms, and anesthetized implanted rats will mark the shift from sensor feasibility to system-level wireless validation.

Single-Shot Precision Decomposition of a 64-Channel FPGA TDC for TOF-PET (#2381)

Giancarlo Sportelli[1,2], Matteo Morrocchi[1,2], Nicola Belcari[1,2]

[1] University of Pisa, Department of Physics "E. Fermi", Pisa, Italy; [2] INFN, Sezione di Pisa, Pisa, Italy

The authors would like to thank TEDIEL s.r.l. for the technical support on FPGA TDC architecture implementation and validation.

Abstract
We report a channel-level characterization of a calibrated 64-channel FPGA Time-to-Digital Converter (TDC) for fast-timing TOF-PET, with explicit decomposition of the single-shot precision (SSP) into quantization and jitter contributions. The TDC is implemented on an Altera Cyclone 10 GX device and operates with a 256-tap, 64-bin tapped-delay-line (TDL) at ~400 MHz, calibrated offline via code-density histograms. Two implementation strategies are compared: the default arithmetic carry-chain inference, and a placement-aware variant in which the TDLs are constrained to regular structures. Across all 64 channels, controlled placement reduces the ultra-bin width from 160 ± 76 ps to 101 ± 12 ps, the equivalent LSB (LSBeq) from 83 ± 32 ps to 63 ± 4 ps, and the quantization noise σ_Q from 24.5 ± 7.3 ps rms to 18.1 ± 0.8 ps rms. The placement-constrained implementation also substantially improves channel-to-channel uniformity. The constrained routing increases σ_{jitter} which makes jitter the dominant SSP contribution once σ_Q is reduced. A system-level projection onto previously characterized UTOFPET monolithic modules indicates that the TDC accounts for 59% of the measured CRT² in a 12 mm LYSO/256-channel module (CRT ≈ 150 ps FWHM), but only ~8% in 16–20 mm BGO/64-channel modules (CRT ≈ 400 ps FWHM). This identifies σ_{jitter} as the dominant architectural ceiling and motivates wave-union/multi-TDC averaging or finer-node FPGAs for full LYSO exploitation.

Education kit for radiation measurements (#2477)

Masaharu Nomachi

The University of Osaka, RCNP, Ibaraki/Osaka, Japan

This work is supported by IEEE/NPSS Initiative.

Abstract
We have been organizing schools on radiation measurements for students from ASEAN countries. Hands-on experience with radiation measurements is very important, and we prepare radiation measurement systems for practical exercises.
To host as many students as possible, we considered organizing the schools in ASEAN countries. However, the shipping cost of the equipment was extremely high. As a result, we could not conduct hands-on exercises on radiation measurement.
Driven by recent large-scale experiments, electronics for radiation measurements have become compact, highly integrated, and low-cost. This development now makes it possible to carry equipment to schools.
Today, compact detector systems are available at affordable prices, making it much easier to conduct practical radiation measurement exercises in schools.
However, modern compact electronics have introduced a new problem: they are too small to probe easily with an oscilloscope. In modern electronics, waveform processing is increasingly performed digitally. Nevertheless, we

believe that analogue processing remains important and highly educational for students. This motivated us to develop electronics specifically for educational purposes.
We have developed an “education kit” for radiation measurement education. By plugging in a SiPM and a small scintillator crystal module, the board functions as a complete radiation measurement system. An on-board FPGA interfaces with a PC through a USB connection. The board is the size of a Raspberry Pi board. Optionally, it can be plugged onto a Raspberry Pi.
Although the board is compact, it provides sufficient space for probing signals. The design of the board will be released as open-source hardware. Students can modify the design and develop their own versions of the board. The “education kit” will serve as an entry point to radiation measurement electronics.

Preliminary Test Results on Latest Version of FESA Readout ASIC for TOF-PET Detectors (#2565)

Yuhao Yang, Yonggang Wang, Xinchi Xu, Xiang Zhang, Huandong Huang

University of Science and Technology of China, Department of Modern Physics, Hefei, China

Abstract
The latest version of the low-power 64-channel Front-End readout chip for SiPM Array (FESA4.0) with the preliminary test results is presented in this paper. Using a row-column summing readout method, FESA compresses the 64 input signals into 16 output digital pulses, which then is digitized by the followed field programmable gate array (FPGA). In the pathway of each summing output, there are two threshold current comparators used for signal pickup, one with a low threshold for signal timing and the other with a high threshold for signal validation. Since the signal amplitude is converted into the pulse time-width via the linear discharge method, both the signals timing and amplitude can be measured by the time-to-digital converter (TDC) in the FPGA. The new version of FESA incorporates a time-over-threshold (TOT) measurement capability, which allows to identify the signals originating from different scintillators. The chip offers prominent advantages of simple architecture, low power consumption, and high performance. Through electronics tests, FESA4.0 has a measurement linearity of 99. 1% with a dynamic range of 140. The intrinsic time measurement precision is measured better than 30 ps. Combined with a TOF-PET detector with an 8×8 LYSO crystal coupled to an 8x8 SiPM, the energy resolution and time coincidence resolution are measured as 279 ps and 12.4% respectively. These test results show that FESA4.0 is very promising for the construction of highly integrated TOF-PET scanners.

SEU Evaluation of an Atom Switch-based FPGA for Slow-Control Systems (#2501)

Kazuki Ueno[1], Nanae Taniguchi[2], Toshitsugu Sakamoto[3], Makoto Miyamura[3]

[1] The University of Osaka, Department of Physics, Osaka, Japan; [2] KEK, Institute of Particle and Nuclear Studies, Tsukuba, Japan; [3] NanoBridge Semiconductor, Inc., Tsukuba, Japan

Abstract

Atom Switch-based FPGAs (AS-FPGAs) are being developed as next-generation FPGAs with expected high radiation tolerance. Their application to various radiation environments is anticipated, and we are also investigating their potential use in detector electronics for future high-energy physics experiments. In this study, neutron irradiation tests were performed to evaluate the Single Event Upset (SEU) tolerance of digital resources implemented in a 65 nm AS-FPGA. A prototype slow-control board equipped with the AS-FPGA was developed and used for the irradiation test. Two independent block RAM (BRAM) blocks and D-type flip-flop (DFF) blocks were implemented in the FPGA for SEU evaluation, and data mismatches detected during irradiation were counted as SEU events. Neutron irradiation tests were carried out using the tandem accelerator at Kobe University. The neutron fluence reached 1.2×10^{11} n/cm^2. No SEUs were observed in the DFF blocks, while approximately 10 SEUs were detected in the BRAM blocks. The preliminary SEU cross section for the BRAMs was estimated to be on the order of 10^{-9} cm^2/Mbit. In parallel with the irradiation studies, stable acquisition of temperature and pressure data from a commercial environmental sensor connected to the prototype slow-control board was successfully demonstrated during neutron irradiation, indicating the applicability of the AS-FPGA to detector slow-control systems in radiation environments.

This work was supported by JSPS KAKENHI Grant Numbers 25KJ1715 and 21H04971.

Abstract
The COMET Phase-I experiment at J-PARC searches for muon-to-electron conversion in muonic atoms, which is a charged-lepton-flavor-violating process. The signal electron is monoenergetic, and its momentum is reconstructed using hit information from the Cylindrical Drift Chamber (CDC) and timing information from the Cylindrical Trigger Hodoscope (CTH). The trigger system must provide high event-selection efficiency, be robust against radiation, return trigger decisions within 8.5 μs, and operate stably. To achieve high event-selection efficiency, a multi-stage hardware trigger system was previously developed in which the CDC and CTH trigger candidates are processed in parallel and required to be in coincidence. However, FPGA reconfiguration in the CDC trigger path could change the communication latency, shifting 10 MHz CDC hit frames and degrading the time consistency required for online track finding. This work reports the development and validation of fixed-latency CDC trigger firmware using a setup with one board of each type. Repeated communication-link reset tests show that the latency is fixed with path-to-path variations less than 1 ns. The total latency is 3.5–3.6 μs, satisfying the requirement with sufficient margin, and input-pulse tests demonstrate 100% trigger response efficiency. These results establish a basis for ongoing full-board CDC validation and CDC–CTH trigger-system integration toward Phase-I data-taking.

Evaluation of a Charge Sharing Compensation with Synchrotron Radiation (#2795)

Piotr G. Maj[1], Dominik S. Gorni[1], Grzegorz W. Deptuch[1], David P. Siddons[2], Abdul Rumaiz[2]

[1] Brookhaven National Laboratory, Instrumentation Department, Upton, USA; [2] Brookhaven National Laboratory, NSLSII, Upton, USA

The work wouldn’t be accomplished without dedication of the high-density interconnection group led by Donald Pinelli at Instrumentation Department at BNL as well as the continuous support Anthony Kuczewski from NSLSII.

Abstract
Charge-sharing compensation results obtained with the 3FI ASIC bump-bonded to a pixelated silicon sensor and tested on an NSLS-II synchrotron beamline are presented. The 3FI is a 32×32-pixel readout ASIC fabricated in 65

nm CMOS for Full-Field Fluorescence spectral X-ray Imaging, with 100 µm pixel pitch and event-driven analog output. Building on previously reported functionality and noise performance, this work focuses on the charge-sharing regime. A micrometer-diameter pinhole beam was stepped across pixel boundaries, and event-by-event charge data were recorded at each position. When the beam is directed precisely between two pixels, raw individual-pixel spectra exhibit split-charge events with degraded energy resolution. Offline charge summation of coincident neighboring pixels restores the full photon energy, recovering spectral integrity at the cost of a √2 noise increase. Furthermore, since the shared event is independently sampled by both neighbors, averaging the two reconstructed values cancels the noise penalty entirely, making the detector effectively insensitive to charge sharing across the inter-pixel region. The correction is validated against single-pixel hits recorded away from pixel boundaries, demonstrating full spectral restoration.

Abstract
As unconventional oil and gas exploration extends toward deep and ultra-deep wells, downhole nuclear logging systems are required to operate under high-temperature, high count-rate, and high energy-precision conditions over a wide dynamic range, which are difficult to simultaneously achieve using conventional pulse sampling methods. The multi-voltage threshold (MVT) technique provides inherent advantages under these constraints; however, conventional power-exponential pulse models exhibit limited robustness to waveform variations among detectors of different types and sizes, resulting in degraded pulse reconstruction accuracy and energy linearity. To address this issue, an energy-linearity optimization method is proposed for MVT-based neutron elemental logging instruments. A dedicated front-end signal conditioning and pulse-shaping circuit was developed to regulate the detector pulse shape for improved matching with the power-exponential model, thereby enhancing fitting accuracy. This approach effectively reduces reconstruction error and improves spectral performance across a wide energy

range. Experimental results demonstrate that the coefficient of determination (R^2) was significantly improved from 0.1380 to 0.9851. The energy resolution was enhanced from 10.5% to 6.2%, closely approaching the oscilloscope-based result of 6.0% with a deviation of only 0.2%. In addition, the proposed method demonstrated good compatibility with detectors of different types and sizes, indicating strong potential for applications in ultra-deep (~10,000 m) and extreme downhole environments.

Abstract
The COMET (COherent Muon to Electron Transition) Phase-I experiment at J-PARC searches for coherent muon-to-electron conversion in aluminum with a single-event sensitivity of 3 x 10^-15. A key detector challenge is the high instantaneous beam rate, which produces background hits in the Cylindrical Drift Chamber (CDC). In particular, low-energy protons can generate large ionization signals that drive the readout electronics into nonlinear regions, producing waveform saturation and pileups. These effects may reduce hit efficiency by masking later signal or background hits and therefore must be modeled realistically in performance studies. We developed a detector response model for the CDC that combines Geant4-based ionization with the Photon Absorption Ionization (PAI) model, Garfield++-based drift time calculation, and an electronics response emulation based on measured response functions. The model explicitly includes nonlinear saturation effects in the circuit and was validated using cosmic-ray test data. The measured-response model reproduces the main features of the data more accurately than a simple linear-response model. The remaining discrepancy corresponds to a limited uncertainty in the pileup-effect evaluation, providing a realistic basis for COMET Phase-I reconstruction and performance studies.

Improving UAV-Based Radiation Monitoring in Mountainous Forests Using ANN with Spectral Information (#1212)

Kazuhiro Suzuki[1,2], Miyuki Sasaki[1], Ayumu Miyahara[1], Yuki Morishita[1], Hironori Funaki[1]

[1] Japan Atomic Energy Agency, Collaborative Laboratories for Advanced Decommissioning Science, Fukushima, Japan; [2] Hirosaki University, Graduate School of Health Sciences, Aomori, Japan

Abstract

Unmanned aerial vehicles (UAVs) are widely used to estimate ambient dose equivalent rates in mountainous forests. However, improving estimation accuracy remains challenging due to complex terrain and forest structure. In this study, an artificial neural network (ANN) model was constructed using UAV measurement data, and its applicability to estimating ambient dose equivalent rates at 1 m above ground level in mountainous forests was evaluated. In addition, the effect of explicitly incorporating direct and scattered radiation components on estimation accuracy was examined. These results show that the proposed ANN-based approach incorporating physically informed spectral information reduces root mean square error by 23% relative to the conventional Flat Source Model in mountainous forests, with explicit separation of radiation components further improving both estimation accuracy and physical interpretability.

Figure-Grounded Multimodal Retrieval-Augmented Generation for Radiation Equipment Manual Question-Answering (#1505)

Minjong Kim[1], Jinhyung Kwon[2], Jonghoon Park[2], Sangmin Lee[2], Byeonghyeon Park[2]

[1] Korea Atomic Energy Research Institute, Applied Artificial Intelligence Section, Daejeon, South Korea; [2] Korea Institute of Nuclear Safety, Radiation Regulation Division, Daejeon, South Korea

This research was supported by a grant from the Korea Atomic Energy Research Institute (KAERI) R&D Program (No. KAERI-526140-26). This work was also supported by a grant from the Korea Institute of Nuclear Safety (KINS), funded by the Nuclear Safety and Security Commission (NSSC) of the Republic of Korea in 2026 (No. 26-24-FD) for the project titled "Development of User-Customized AI-Based Radiation Equipment Management System."

Abstract

Radiation equipment manuals are multimodal documents in which textual content and safety-related visual materials jointly carry critical information. Existing retrieval-augmented generation (RAG) methods are predominantly text-centric and either fail to reflect visual information or include figures unrelated to the answer. This paper proposes a figure-grounded multimodal RAG pipeline that delivers an answer together with its supporting figures. The proposed method comprises figure-to-section alignment via a document map, hybrid sparse–dense retrieval, and answer generation accompanied by relevant figures. To evaluate multimodal performance, we construct an answer-grounded ground-truth figure set and define Figure Precision@k and Figure Recall@k as evaluation metrics. On a benchmark of ten radiation-equipment manuals (800 questions), the proposed method improves Figure Precision@5 from 0.06 to 0.30 and Figure Recall@5 from 0.15 to 0.61 over an image-embedding baseline, with textual answer quality comparable to a long-context text-RAG baseline in BERTScore-F1 and slightly lower in ROUGE-L.

Physics Enhanced Machine Learning for Thermoluminescence Glow Curve Deconvolution (#1623)

Lukasz Tomaszewski, Caroline Shenton-Taylor

University of Surrey, Department of Physics, Guildford, UK

This work was funded and supported by the Nuclear Threat Reduction Network (NTR-Net), UK Ministry of Defence
© Crown Owned Copyright 2026/AWE.

Abstract

Thermoluminescence dosimetry (TLD) relies on accurate glow curve deconvolution to characterise trapping parameters, yet conventional methods are computationally intensive and rely on expert-defined initial parameters. This study explores a machine learning (ML) framework to automate glow curve analysis while preserving interpretability and decreasing user input. A hybrid CNN–GRU model was developed and trained on 658 experimental glow curves from silica glass beads and 10,000 synthetic mathematical glow curves derived from kinetic order equations. The model demonstrates the ability to reconstruct glow curves and infer peak structures without explicit user-defined initialisation, achieving an average figure of merit (FOM) of 8.3% on unseen experimental data. Notably, the ML approach consistently identifies the primary glow peak at the same temperature positions as conventional deconvolution methods, indicating that prominent physical features are reliably captured. Although traditional deconvolution techniques yield lower FOM values (~1%), they require optimisation and expert guidance. However, the ML model provides rapid, repeatable predictions and scales efficiently to large datasets. The results suggest that ML is not a replacement for conventional approaches but a complementary tool, in which ML predicts the initial parameters rather than a user. This work highlights the potential for hybrid ML-physics strategies to advance TL analysis.

A High-Fidelity Robotics Simulation Framework for Autonomous Radiation Source Search (#2144)

Lance M. Drouet[1,2], Kalie Knecht[2], John Sparger[2], Michael Willis[2], Peter Sobel[2], Nicholas Prins[2], Jason Karcz[2]

[1] University of Tennessee, Department of Nuclear Engineering, Knoxville, USA; [2] Oak Ridge National Laboratory, Oak Ridge, USA

This research was supported by the U.S. National Nuclear Security Administration (NNSA) Office of Defense Nuclear Nonproliferation Research and Development within the U.S. Department of Energy under Contract AC05-00OR2272.

Abstract

Radiological source search requires timely threat assessment to ensure the security of the public. Existing methods rely on personnel to conduct radiation surveys with mobile detector systems, potentially exposing them to hazardous environments. Recent advancements in physical AI have presented the opportunity to improve radiological source search with robotics, machine learning, and artificial intelligence. Prior work at Oak Ridge National Laboratory (ORNL) has developed a radiation search platform that equips the Boston Dynamics Spot quadruped with a radiation imager, LiDAR, IMU, camera, and onboard computer for real-time 3D radiation imaging during autonomous navigation of complex environments. However, the development and field testing of autonomous robotic platforms are resource intensive and operationally constrained, motivating a simulation framework to refine autonomy algorithms and evaluate search performance across complex environments that would otherwise be infeasible to access. Building on the physical system, this work presents a high-fidelity simulation framework for developing and testing autonomous radiation search workflows in NVIDIA Isaac Sim. The framework centers on a model of the Spot quadruped equipped with simulated contextual sensors, including 3D LiDAR, RGB, and depth cameras, and exposes velocity-command control through a ROS 2 bridge. The current implementation provides end-to-end integration of sensor streaming, command interfaces, and a Python-based autonomy pipeline. Preliminary mapping outputs are presented as qualitative system-integration results and sandbox visualizations to support future autonomy and radiation-modeling studies.

Robust Dual-Target Radioisotope Quantification Under Increasing Unseen Contaminant Complexity (#2217)

Chanho Kim[1], Yeongjun Kim[1], Geon Kim[2], Dae yang Oh[2]

[1] Korea Atomic Energy Research Institute, Daejeon, South Korea; [2] Korea University, Department of Bioengineering, Seoul, South Korea

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (Ministry of Science and ICT) (No. RS-2022-00165164).

Abstract

Gamma-ray spectroscopy is a fundamental technique for radioisotope identification and quantification across safety-critical applications, where deep learning models have recently emerged as a data-driven alternative to traditional library-dependent methods. However, most existing deep learning approaches operate under a closed-set assumption that all isotopes during deployment are present in the training set; field deployments frequently violate this assumption, and the introduction of unknown isotopes leads to silent degradation. Recent OOD-detection studies have been reported, but they treat OOD spectra as anomalies to be flagged rather than quantified, and systematic evaluation under increasing unseen contaminant complexity remains lacking. This study proposes a denoising autoencoder (DAE) framework that reconstructs the clean target spectrum (^{137}Cs, ^{133}Ba) from contaminated measurements while simultaneously estimating target fractions through a dual-head architecture. Using Ce:GPS scintillator pulse data under a leave-one-out unknown noise (LOO-UN) protocol, the DAE achieved a mean absolute error (MAE) of 0.024 at 20% out-of-distribution (OOD) contamination in the two-unseen configuration, outperforming NNLS-known (0.038) and MLP (0.031), with near-constant accuracy as the unseen contaminant count increased from one to two (0.025 → 0.024).

This work was supported by the Danish Data Science Academy, funded by the Novo Nordisk Foundation (NNF21SA0069429) and the VILLUM FONDEN (40516). The first author also acknowledges the i-RASE (Intelligent Radiation Sensor Readout System) project team for their support and collaboration.

Abstract

Bridging the *MeV gap* remains difficult due to the interplay of competing photon interaction processes, leaving a persistent sensitivity gap in gamma-ray astronomy. Compton telescopes based on 3D CZT Drift Strip Detectors (DSD) are promising candidates for bridging this gap, offering room-temperature operation, high stopping power, excellent energy and position resolution. A key open question is whether recoil electron tracking, which significantly improves angular resolution and detector sensitivity is achievable from raw detector signals. We investigate this using a machine learning approach trained on forward simulations of the 3D CZT DSD response. Principal Component Analysis of simulated electron tracks confirms that track structure is encodable in a low-dimensional representation, and neural network training to regress the recoil direction directly from detector waveforms is ongoing.

Enhanced Spent Nuclear Fuel Characterization Using Sequential Detector Responses through Deep Learning (#2393)

Beomkyu Kwon[1], Wooseong Hong[1,2], Jaehyo Kim[1,2], Geehyun Kim[1,2]

[1] Seoul National University, Nuclear Engineering, seoul, South Korea; [2] Seoul National University, Energy Systems Engineering, seoul, South Korea

This work was supported by the Nuclear Safety Research Program through the Korea Foundation of Nuclear Safety (KoFONS) using the financial resource granted by the Nuclear Safety and Security Commission (NSSC) of the Republic of Korea. (RS-2022-KN073410)

Abstract

Accurate characterization of spent nuclear fuel (SNF) is essential for verifying operator-declared information in nuclear safeguards. Conventional nondestructive assay (NDA) approaches for such characterization based on gamma-ray spectroscopy typically rely on extracting specific photopeak information (ex. 662 keV peak of ^{137}Cs), which compresses high-dimensional detector responses into a limited number of variables and may lead to information loss. To address this limitation, we propose a deep learning–based SNF characterization approach that directly utilizes sequential detector-response data for advanced characterization performance. The training dataset was generated through integrated ORIGEN and MCNP simulations for 5000 realistic SNF conditions, covering variations in initial enrichment, burnup, and cooling time. The proposed C2C-GRU-v2 architecture was designed to process long sequential detector-response data by combining Coordinate-to-Context embedding and GRU-based recurrent sequence modeling, enabling both event-level contextual learning and sequence-level generalization. For comparison, a conventional spectrum-based regression method using ^{137}Cs peak counts was also implemented under identical conditions. The proposed approach demonstrated improved characterization performance compared with the conventional method, particularly for cooling time estimation, achieving Relative Root Mean

Square Errors (RRMSE) of 0.157 for burnup and 0.0456 for cooling time prediction. These results demonstrate the feasibility of deep learning–based sequential detector-response analysis for advanced SNF characterization in nuclear safeguards applications.

Development of a PINN-Based Defect Verification Algorithm for CANDU Spent Nuclear Fuel Bundles (#2403)

Juwan Kang[1], Yoon Soo Chung[1], Jiwon Ra[1], Jae Joon Ahn[2], Yong Hyun Chung[1]

[1] Yonsei University, Department of Radiation Convergence Engineering, Wonju-si, South Korea; [2] Yonsei University, Division of Data Science, Wonju-si, South Korea

This work was supported by the Nuclear Safety Research Program through the Korea Foundation Of Nuclear Safety (KoFONS) using the financial resource granted by the Nuclear Safety and Security Commission (NSSC) of the Republic of Korea (No. RS-2024-00405144)

Abstract

The 37-element CANDU (CANadian Deuterium Uranium) spent fuel bundles at the Wolsong heavy water reactor are stored vertically in 19 layers within a wet storage facility. The Improved Optical fiber-based VErification System (IOVES), comprising a scintillator, optical fiber, and photomultiplier tube, traverses vertically between bundles to measure radiation profiles. Operators manually count profile peaks to verify bundle integrity, but reliability degrades when peaks are indistinct.

This study presents a Physics-Informed Neural Network (PINN)-based algorithm for automated defect verification of spent fuel bundles. The model learns physical characteristics of radiation profiles to generate predicted profiles, which are compared against measured profiles to localize defective bundles.

A three-head output structure independently predicts the defect status per layer, the number of defective bundles per layer, and the left/right defect probability. The total loss, comprising the three head-specific losses and a mean squared error profile of prediction loss, was optimized using the Adam optimizer.

The dataset comprised three scenarios (0, 1, and 2 defective bundles), with 200,000 samples each, totaling 600,000 samples, split 70%, 15%, and 15% for training, validation, and testing.

Defect classification accuracy per layer reached 99.7%. 19-layer exact match accuracy was 97.2%, with 100% accuracy on defect-free arrays.
This work demonstrates the feasibility of an automated verification system that overcomes operator-dependent inspection limitations. Future work will target improved left/right defect localization accuracy.

Towards Spiking Neural Network-Inspired In-Pixel Processing for Radiation Detectors (#2446)

Anna Kozioł

AGH University of Krakow, Department of Measurement and Electronics, Cracow, Poland

The research leading to these results has received the Dean's financial support from the Faculty of Electrical Engineering, Automation, Computer Science and Biomedical Engineering at the AGH University of Krakow.

Abstract
This work introduces a neuromorphic in-pixel processing concept for next-generation high-flux radiation detectors. By leveraging event-driven principles inspired by Spiking Neural Networks, the proposed approach aims to move part of the signal interpretation directly into the pixel matrix, rather than relying solely on external readout and post-processing. This enables local extraction of photon timing, energy-related features, and mitigation of pile-up effects under extreme photon flux conditions. The concept builds on recent developments in hybrid pixel detectors and emerging intelligent in-pixel architectures, and extends them towards fully event driven detector operation. The proposed paradigm may open new directions for adaptive, low-latency radiation imaging at future synchrotron and XFEL facilities.

CVAE-Based Synthetic Thermoluminescence Silica Glass Jewellery Bead Glow Curve Generation (#2606)

Lukasz Tomaszewski, Caroline Shenton-Taylor

University of Surrey, Department of Physics, Guildford, UK

This work was funded and supported by the Nuclear Threat Reduction Network (NTR-Net), UK Ministry of Defence
© Crown Owned Copyright 2026/AWE.

Abstract
Micro silica glass jewellery beads have emerged as a viable material for thermoluminescence dosimetry (TLD), offering a low-cost and widely accessible option for personal dose assessment. Their linear glow curve responses, governed by irradiation, thermal conditions, and sample characteristics, exhibit unique spectral elements and structure variability. While machine learning (ML) methods have been successfully applied to dose estimation and irradiation analysis, can ML be used to elevate silica glass beads beyond just decorative jewellery? In this work, a Conditional Variational Autoencoder (CVAE) is implemented to model and generate thermoluminescent glow curves from silica glass beads conditioned on experimental parameters. The model is trained on a dataset of experimentally acquired responses, augmented with Poisson noise to increase the dataset size and robustness. Conditioning variables include temperature profiles, irradiation and sample characteristics, enabling the model to learn relationships between physical conditions and the glow curve. Results show that the CVAE model can generate realistic glow curves that reflect the underlying conditioning variables. Generated predications maintain peak structure and overall shape, while also reproducing the expected linear relationship between total counts and absorbed dose. Model performance remains consistent when evaluated on previously unseen testing data with a mean figure of merit of 7.5%, although accuracy declines at low dose levels due to diminished signal intensity. The proposed approach demonstrates the potential of generative ML techniques for supporting dosimetry simulation, calibration, and data augmentation workflows for future research.

This work was supported by the National Research Foundation of Korea and Commercialization Promotion Agency for R&D Outcomes (RS-2023-00234651).

Abstract

In radiation-guided cancer surgery, the amount of radioactive isotopes administered is limited, resulting in the acquisition of low-count, low-resolution gamma images that are further degraded by scattered radiation. In this study, a Residual Convolutional Autoencoder (Residual CAE) was developed to suppress background noise and enhance source-related signals in low-count [if gte msEquation 12]><m:oMath><span lang=EN-US style='font-size:8.0pt; mso-bidi-font-size:10.0pt;font-family:"Cambria Math",serif;mso-fareast-font-family: "맑은 고딕";mso-fareast-theme-font:minor-fareast;mso-bidi-font-family:"Times New Roman"; mso-ansi-language:EN-US;mso-fareast-language:EN-US;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>13</m:r><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>×</m:r><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>13</m:r></m:oMath><![endif] gamma-ray images. The input images were zero-padded to [if gte msEquation 12]><m:oMath><span lang=EN-US style='font-size:8.0pt;mso-bidi-font-size:10.0pt; font-family:"Cambria Math",serif;mso-fareast-font-family:"맑은 고딕";mso-fareast-theme-font: minor-fareast;mso-bidi-font-family:"Times New Roman";color:black;mso-ansi-language: EN-US;mso-fareast-language:EN-US;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>16</m:r><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>×</m:r><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>16</m:r></m:oMath><![endif] and normalized by the image-wise maximum value. The Residual CAE was configured as an encoder-decoder network with a residual connection that adds the first shallow feature map to the final decoder feature map, thereby preserving source location and spatial details. In test results, the Residual CAE achieved an MSE of 0.0007, SSIM of 0.9682, peak bias of 0.2416 pixels, and [if gte msEquation 12]><m:oMath><span lang=EN-US style='font-size:10.0pt; font-family:"Cambria Math",serif;mso-fareast-font-family:"맑은 고딕";mso-fareast-theme-font: minor-fareast;mso-bidi-font-family:"Times New Roman";mso-ansi-language:EN-US; mso-fareast-language:EN-US;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="b"/></m:rPr>Δ</m:r></m:oMath><![endif] FWHM of 0.0441 pixels. To enable direct deployment of the trained model on the gamma camera and the monitoring software the model was converted to the Open Neural Network Exchange (ONNX) format, allowing its inference performance to be evaluated in an

embedded environment. The entire deployment pipeline, including preprocessing, inference, and postprocessing, was implemented. The converted ONNX model produced outputs that were highly consistent with the trained model and demonstrated low-latency inference suitable for real-time gamma-ray image processing. After conversion to ONNX, the model maintained reliable inference performance, achieving a mean peak bias of 1.35 pixels, a minimum Δ FWHM of −0.711 pixels, and 95.73% overall classification accuracy. These results demonstrate that the Residual CAE is effective for gamma-ray image denoising and source enhancement while preserving source localization and spatial resolution, supporting its feasibility for real-time deployment.

Neural-Network Surrogate Modeling of TID-Induced Degradation in 180 nm Bulk NMOS Transistors (#2739)

Minuk Seung, Seop Hur, Chanho Kim

Korea Atomic Energy Research Institute, Daejeon, South Korea

This work was supported in part by the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (RS-2022-00144324, RS-2022-00165164 and RS-2023-00258052).

Abstract
This paper presents a neural-network surrogate model for predicting Total Ionizing Dose (TID) induced degradation in a 180 nm bulk CMOS NMOS transistor. The proposed model uses only the gate length L, gate width W, W/L, total dose, and log(1+dose) as input features, where the layout parameters are extractable from a PDK netlist. The model predicts the dose-dependent changes in V_{th}, I_{on}, I_{off}, g_m, and SS. Using 180 nm NMOS data generated by a 3D drift-diffusion TCAD framework, the model is evaluated under three holdout conditions: 15 kGy(SiO_2) interpolation, 50 kGy(SiO_2) extrapolation, and a held-out geometry (L, W)=(240nm, 750nm). With 3-fold cross-validation along the dose axis and five random-seed repetitions, the worst-case absolute relative errors of V_{th}, I_{on}, g_m, and SS are below 0.30% in the INTERP/EXTRAP conditions, while those of I_{off} are 0.99–1.45% and 2.16–

2.52%, respectively. In the held-out geometry condition, the worst-case errors of all five metrics remain within 2%, indicating that TCAD-level TID degradation trends can be approximated using layout and total dose variables.

Deep Learning Positioning and Depth of Interaction Prediction with Automatic Gain Mismatch Correction (#2882)

Matthew Dilsizian, Hongdi Li, Yusheng Li

United Imaging, Molecular Imaging, Houston, USA

Abstract

This paper describes a deep learning algorithm for the estimation of axial, transverse, and depth of interaction (DOI) positions of detected events in SPECT. The algorithm includes a method for automatic calibration of the gain factor mismatches between detectors. The training data is obtained by simulation. The model consists of three feed-forward networks, one for each parameter to estimate. The axial is a continuous estimate, while transverse and DOI and discrete. The axial estimate is passed as an additional parameter to the DOI estimate, which improves estimates near the detector edge. A single base model is trained with data from a reference detector that is taken to have perfect gains, then calibration learns factors relative to this detector. Log-gains are learned to smoothly enforce strict positivity, from which the gains can be easily recovered. The algorithm achieves an axial FWHM of 1.40 mm, transverse FWHM of 0.83 mm, and a DOI FWHM of 1.24 mm. The gain factor estimates, based on histogram data, are within 0.001%.

Deep learning for precise gamma-ray interaction in an hexagonal monolithic scintillation crystals for PET imaging (#2968)

Lidia Jiménez Algarra[1], David Pérez-Benito[1], David Izquierdo-Garcia[1], Juan J. Vaquero López[1,2]

[1] Universidad Carlos III, Departamento de Bioingeniería, Leganés, Spain; [2] Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Abstract

The estimation of scintillation positioning with a high degree of precision in PET detectors is a crucial factor in determining the spatial resolution of the final image. Nevertheless, intra-crystal Compton scatter, optical diffusion, edge effects, and DOI ambiguity collectively limit the accuracy of first-interaction localization. Consequently, reducing this uncertainty will have a significant impact on the LOR definition and, in turn, will enhance the quality of the final PET image. Machine learning and deep learning methodologies have been shown to be particularly effective in this domain, resolving non-linear relationships between data and often outperforming other traditional approaches. In this study, we investigate various pipelines and deep learning techniques for enhancing gamma-positioning precision through the utilization of validated Monte Carlo simulations in a monolithic PET crystal with a specific hexagonal-shaped scintillation crystal. The validation of the selected models was done using experimental data specifically acquired for this study. The findings suggest that the most effective approach involves the utilization of a net trained with photoelectric and scatter events. The final FWHM mean in the corner and center are 1.2 mm and 1.7 mm for the simulated data respectively, while 1.74 and 2.63 mm, respectively for the validation. The bias achieved was 0.25 mm in the Z direction for the simulation.

Characterizing Neutron Detection Efficiency in Timepix3: A Bayesian-Optimized FLUKA Approach (#3239)

Angel Mercado, Sharmistha Mukhopadhyay, Malachi West, Patrick Connolly, Shaheen Dewji

Georgia Institute of Technology, Atlanta, USA

Abstract

Characterization of converter layer geometry is critical for determining the absolute detection efficiency of pixelated thermal neutron detectors. However, uncertainties in film deposition and source strength often lead to significant

discrepancies between simulated models and actual experimental performance. This work addresses these challenges by implementing a Bayesian optimized FLUKA framework to determine the effective enriched Lithium-6 Fluoride converter thickness for an ADVACAM Timepix3 detector with a 1000 µm Silicon sensor. The FLUKA Monte Carlo model was benchmarked against experimental measurements using an Americium-Beryllium source with a nominal activity of 40 mCi and a documented tolerance of fifteen percent. The Bayesian optimizer successfully converged to an effective thickness of 5 µm after forty evaluations by minimizing the residuals between the nominal source activity and the simulation-implied activities. This methodology demonstrates a robust approach to resolving geometric uncertainties in hybrid semiconductor detectors where direct physical measurement of internal components is not feasible post-assembly. The resulting validated geometry provides a high-fidelity foundation for modeling future detection efficiency benchmarks across diverse neutron spectra. This work demonstrates a practical approach for integrating machine-learning optimization with Monte Carlo transport modeling to address geometric uncertainties in neutron detectors.

Background pattern recognition and its reconstruction during radiation shadowing by scanned vehicles in Radiation Portal Monitors. (#1109)

Vladislav Kondrashov

GalaxRay LLC, radiation detectors, Mississauga, Canada

We are grateful to Dr. Eva Rimbauer, ALARA expert for her review and invaluable advices.

Abstract
The author has presented the approach to ambient radiation background pattern recognition and reconstruction for plastic scintillator-based Radiation Portal Monitors during vehicle scanning in situations when the ambient background is depressed (shadowed) by a vehicle. The principle is based on a correlation-significance test derived from the paired Student's t-tests and Pearson correlation coefficients. The author establishes criteria to recognize background depression and radiation source presence in the occupancy spectrum.
After determining the scale of depression for defined energy windows, the given approach presents the formalism to reconstruct the depressed background during the scan which is based on Aluminum variable thickness sheet as a vehicle equivalent model and the method for evaluating the signal-to-noise ratio to detect the radiation source under such scan conditions.

Effect of Source Intensity Imbalance on Two-Point Angular Resolution in Coded-Aperture Imaging (#1160)

Yuhang Qiu[1], Tiantian Dai[2], Qingyang Wei[1]

[1] University of Science and Technology Beijing, School of Automation and Electrical Engineering, Beijing, China; [2] China-Japan Friendship Hospital, Department of Radiation Oncology, Beijing, China

This work was supported by Project “Vice President of Science and Technology” of Changping District, Beijing (Grant No. 202503003030).

Abstract

Far-field angular resolution of coded-aperture gamma-ray imagers is often assessed by the smallest angular separation at which two point sources can still be distinguished, but the effect of unequal source activities on such measurements remains unclear. In this work, Monte Carlo simulations were performed to quantify how source-count imbalance influences two-point-source resolution tests in coded-aperture imaging. Images were reconstructed using the maximum-likelihood expectation-maximization algorithm, and reconstruction quality was evaluated using the valley-to-weak-peak ratio and localization bias. An appropriate stopping point was determined by jointly examining both metrics. Under ideal noise-free conditions, increasing source-count imbalance progressively degraded two-source discrimination. When the valid-count mismatch did not exceed 20%, acceptable discrimination was maintained near the nominal angular resolution limit, whereas larger mismatches caused a marked increase in localization bias. These results indicate that source-count imbalance can bias two-point-source resolution measurements and should be controlled in practical evaluations of coded-aperture systems.

X-Ray Measurement of Tubes Using Closed-Loop Residual-Driven Optimization Algorithm (#1269)

Yuchang Sun, Tianchen Zeng, Liqiang Wang

Tsinghua university, Bejing, China

Abstract

The geometric cross-sectional parameters of circular tubes, such as cables and rubber hoses, including inner and outer diameters, wall thickness, and eccentricity, are key indicators of manufacturing quality. However, existing X-ray digital imaging-based inspection methods generally rely on locating edge transition points (ETPs) in attenuation profiles, which degrades the accuracy and reliability of parameter reconstruction. To address these limitations, this paper develops a closed-loop residual-driven optimization (CRO) algorithm. The residual at ETPs between the measured projection and the analytical projection of the parameterized contour model is used as the feedback signal, and the contour parameters are corrected through a sign-driven update rule. Monte Carlo (MC) simulation data as the measured data demonstrates that, for a detector pixel size of 0.04mm, introducing CRO reduces the MAE of contour parameters by 69.44%, with a maximum error of 0.03mm.

Verification of a Rapid Dose Assessment Program Against MCNP for Nuclear Power Plant Decommissioning (#1310)

Changyeon Yoon

Korea Hydro & Nuclear CO., LTD, Central Research Institute, Daejeon, South Korea

Abstract

Accurate prediction of radiation exposure for workers during nuclear facility decommissioning is important for radiation protection and work planning. To support this, a previously developed dose assessment program based on the Electric Power Research Institute (EPRI) algorithm was verified in this study. The program inversely estimates source activity from known source positions and measured dose rates at selected locations, and then calculates worker exposure based on the estimated activity. To verify the performance of the program, its results were compared with those from MCNP, a widely used Monte Carlo radiation transport code. Three representative scenarios were considered: (1) multiple workers and multiple sources, (2) presence of thick shielding, and (3) changes in shielding and source location. For each scenario, dose rates were first calculated using MCNP and used as reference values, and the developed program predicted doses under the same conditions. In addition, the Average Fractional Error (AFE) was evaluated by comparing the measured dose rates with the dose rates recalculated at the same points using the estimated source activity. The results show that the prediction error is within 10% for most cases, while the shielding scenario shows a higher deviation, with a maximum error of 18.2%. The AFE results also support this trend, with a maximum value of 34% for the shielding case and less than 6% for the other scenarios, which are within the acceptable range based on the EPRI algorithm criterion. These results indicate that the program provides reliable results overall, while some deviation appears under strong shielding conditions. Since decommissioning environments change frequently, repeated MCNP simulations can be time-consuming. The developed program provides results within a few seconds, allowing quick estimation of worker dose under changing conditions and supporting practical work planning.

High-Reliability Tritium Monitoring Using Hardware Alpha Suppression and AI-Based Smoothing Filter (#1370)

Sungho Lee

Korea Atomic Energy Research Institute, Department of Radiation Safety Control, Daejeon, South Korea

This work was supported by KAERI R&D Program (No. KAERI-522430-26)

Abstract

Tritium monitoring in research reactors is essential for radiation safety because tritium is released as a low-energy beta emitter and is therefore difficult to measure accurately in real time. In particular, the reliability of tritium measurements can be degraded by two major factors: unavoidable statistical fluctuations in the ion chamber output and transient interference caused by radon and its alpha-emitting progeny. Radon-induced alpha events generate large ionization signals in the ion chamber, producing spike-like transients that can distort the measured current, while statistical fluctuations reduce the stability and precision of the monitoring data. To address these limitations, this study proposes a tritium monitoring system that combines a hardware-based alpha suppression function with an AI-based smoothing filter. The proposed monitor consists of two ion chambers, a pump, and a membrane separator, enabling gamma compensation and the exclusion of beta-emitting noble gases. The alpha suppression circuit detects and removes alpha-induced transients before they affect the measurement output. In addition, a piecewise learning-based smoothing filter is applied to reduce statistical fluctuations while preserving the response to actual changes in tritium concentration. The filter employs a two-stage framework consisting of change point detection and local regression, and is implemented using ONNX Runtime in a C#-based real-time monitoring system. Experimental results show that the proposed approach improves both measurement stability and responsiveness, demonstrating its applicability to reliable tritium monitoring in research reactor stack environments.

Automated Monte Carlo-Based Efficiency Transfer Integrated into HPGe Gamma Spectroscopy Workflows for High-Throughput Laboratories (#1579)

Spencer Behling[1], Felix Diel[3], Marc Breidenbach[2]

[1] Ametek, Ortec, Oak Ridge, USA; [2] AMETEK GmbH, Meerbusch, Duesseldorf, Germany; [3] AMETEK GmbH, InnoRIID, Duesseldorf, Germany

Abstract

High-purity germanium (HPGe) detector systems are widely used for gamma spectroscopy; however, increasing throughput demands, expanding measurement configurations, and a declining base of expert users have made traditional efficiency calibration and transfer workflows increasingly impractical. Efficiency transfer between counting geometries has historically required manual configuration, custom made sources, and/or execution of Monte Carlo simulations by trained computational physicists, limiting scalability in routine laboratory environments. We present an approach that embeds Monte Carlo-based efficiency transfer directly within a commercial spectral analysis software stack, enabling automated operation without additional user intervention. At runtime, sample geometries—already specified by laboratory personnel using standard container templates such as Marinelli beakers—are used to drive a ray-tracing-based gamma transport simulation coupled to detector interaction and pulse-processing models. The approach operates over an energy range of 20 keV to 2.5 MeV and produces both full spectra and efficiency curves.

Validation is performed through comparison of simulated spectra and efficiency curves against measured data and results from the Geant4 Monte Carlo toolkit. While not intended to match the full generality of Geant4, the proposed approach demonstrates comparable practical accuracy for routine laboratory configurations while significantly reducing user complexity. Additionally, seamless integration into existing workflows is demonstrated, enabling non-expert users to apply physics-based efficiency transfer without specialized training.
This work provides a scalable solution for automated, high-throughput gamma spectroscopy, bridging the gap between rigorous Monte Carlo modeling and practical laboratory usability.

NSS-13-194

Graph-Based Modeling of Organ and Lesion Radiomics Interactions in Theranostic SPECT/CT Imaging (#3206)

Mohamed Saber Azimi[3], Maryam Cheraghi[4], Mohammad A. Ghodsi-Rad[4], Ghasemali Divband[5], Habib Zaidi[1,2]

[1] Geneva University Hospital, Division of Nuclear Medicine & Molecular Imaging, Geneva, Switzerland; [2] Odense University Hospital, Deptartment of Nuclear Medicine, Odense, Denmark; [3] Obuda University, University Research and Innovation Center, Budapest, Hungary; [4] Shahid Beheshti University, Department of Nuclear Medicine, Tehran, Iran; [5] Jam Hospital, Department of Nuclear Medicine, Tehran, Iran

Abstract
Current radiomics approaches primarily focus on individual organs or lesions, which limits the ability to describe interactions within the body holistically. To address this limitation, we introduce a graph-based framework for modeling radiomics relationships between organs and lesions in theranostic SPECT/CT imaging. A cohort of 57 patients treated with ^{177}Lu-based radiopharmaceuticals was analyzed using post-therapy SPECT/CT. Organs were segmented using a deep learning–based approach, and lesions were delineated semi-automatically on SPECT images. From each region, 107 standardized radiomic features were extracted. Interactions between organs and lesions were quantified using a combination of linear similarity measures (Pearson, Spearman, cosine) and a nonlinear dependency metric based on normalized mutual information. These relationships were then represented as patient-specific graphs to capture system-level radiomics organization. The results reveal a non-uniform interaction pattern, where only a subset of organs exhibits strong associations with lesion characteristics. The highest coupling was observed in physiologically active regions such as the kidneys, liver, and spleen, with normalized mutual information values reaching approximately 0.66. Across all regions, nonlinear dependencies consistently showed higher values than linear metrics, indicating that complex relationships dominate radiomics interactions. Network representations further demonstrated a densely connected structure without prominent hubs, suggesting a distributed interaction model. Stability analysis confirmed reproducible patterns across patients, with near-perfect rank consistency and high agreement among top-ranked regions. These findings demonstrate that radiomics interactions between organs and lesions are structured, nonlinear, and reproducible. The proposed framework enables system-level interpretation of imaging data and may support the development of more informative biomarkers.

Quantitative Neutron Emission Tomography of Plutonium-Bearing Materials using a Boron-Coated Straw Detector Array (#2009)

David Breitenmoser[1], Ming Fang[2], David L. Chichester[3], Scott Thompson[3], Shaun D. Clarke[1], Angela Di Fulvio[2], Sara A. Pozzi[1]

[1] University of Michigan, Department of Nuclear Engineering and Radiological Sciences, Ann Arbor, USA; [2] University of Illinois, Department of Nuclear, Plasma, and Radiological Engineering, Urbana-Champaign, USA; [3] Idaho National Laboratory, Radiochemistry and Nuclear Measurements Department, Idaho Falls, USA

This work was funded in part by the Department of Energy through award number DE-NE0009507 “Non-Destructive Plutonium Assay in Pyroprocessing Bulk Materials with a 3D Boron-Coated-Straw Detector Array”.

Abstract

Neutron-based non-destructive assay (NDA) is a cornerstone of nuclear safeguards. Yet conventional techniques relying on integral counting suffer from significant biases if the spatial distribution and emission strength of neutron sources are unknown. This work presents a new, quantitative neutron emission tomography framework using a custom boron-coated straw detector array, enabling simultaneous localization and emission rate estimation of plutonium-bearing materials. Using high-fidelity Monte Carlo simulations and a custom iterative support-refined non-negative least squares algorithm, we demonstrate that centimeter-scale spatial resolution and percent-level accuracy in emission rate reconstruction can be achieved for realistic counting statistics. These results highlight the potential of neutron emission tomography as a next-generation NDA technique for advanced nuclear fuel cycles and reprocessing technologies.

NSS-13-198

Caesium 137 Radiation Transport Profile Modelling for Application to Physical and Simulation Environments (#2147)

Emmanuel Leo, Kelum A.A. Gamage, Olaoluwa R. Popoola

University of Glasgow, James Watts School of Engineering, Glasgow, UK

Supervisors: Prof. Kelum A. A. Gamage, Dr. Olaoluwa R. Popoola

Abstract

Towards the assembly of a virtual component of a radiological monitoring digital twin, an analysis of Caesium 137's mixed field radiation transport is presented. Caesium 137 decays by both beta and gamma radiation which can allow for long range detection of radioactive leakage events. First, a preliminary screening of the source-to-sensor distances of electrons in air was undertaken using the NIST ESTAR dataset. Following this, a Geant4 study was developed to investigate the profile of Caesium 137 activity with respect to distance from a source and threshold variation. This study confirmed that detection efficiency diminished with increased sensor thresholds and confirmed that the change in activity with respect to distance closely follows Poisson statistics. This sets the ground for creating engineering surrogate models that could be employed for application to the radiation field models and the creation of a physical simulation for radiation. The work carried out enables the application of digital twin methodologies to facilitate semi-autonomous radiological monitoring in Nuclear Power Plant environments.

Bayesian Filtering Image Reconstruction for SourceLocalization and Tracking in Compton Imaging (#2167)

John Leland[1], Cecilia Tarpau[2], Ming Fang[1], Yoann Altmann[3], Angela Di Fulvio[1]

[1] University of Illinois Urbana-Champaign, Nuclear, Plasma, and Radiological Engineering, Urbana, USA; [2] University of Edinburgh, Maxwell Institute for Mathematical Sciences, Bayes Center, Edinburgh, UK; [3] Heriot-Watt University, School of Engineering and Physical Sciences, Edinburgh, UK

This material is based upon work supported in part by the Department of Energy National Nuclear Security Administration through the Nuclear Science and Security Consortium under Award Number DE-NA0003996.

Abstract

Stand-off detection of special nuclear materials (SNM) in safeguards and non-proliferation applications demands imaging systems capable of tracking sources across dynamic environments. In this work, we introduce a Bayesian-Filtering (BF) algorithm for simultaneous source localization and tracking where existing reconstruction methods, such as simple back-projection (SBP) and maximum likelihood expectation maximization (MLEM), are insufficient. We evaluate the BF algorithm using synthetic data generated with MCNPX-PoliMi for a simulated Compton imager consisting of a 4 x 7 array of LYSO scintillator crystals. Two independent sources are simulated, one sweeping in azimuth and one in elevation, each traveling from -90° to +90° at 1 m/s. The BF algorithm successfully tracked both sources across the full angular sweep, achieving mean angular errors of 6.4° and 6.03° for the azimuth and elevation cases, respectively. Additionally, preliminary results for multi-source tracking are successful with the algorithm tracking both sources up until their paths intersect which is a known challenge we are currently investigating.

An Iterative Based Gain Calibration Method for Multi-Channel Readout Scintillation Detectors (#2248)

Zijun Yan, Yangyang Zhao, Qingyang Wei

University of Science and Technology Beijing, Beijing Engineering Research Center of Industrial Spectrum Imaging and School of Automation and Electrical Engineering, Beijing, China

This work was supported in part by the National Key Research and Development Program of China under Grant 2022YFC2402001;and in part by Beijing Natural Science Foundation (Grant Number: L232126); and in part by National Natural Science Foundation of China (Grant Number:12375337)

Abstract

To address the common issue of channel gain non-uniformity in multi-channel readout scintillation detectors, this paper proposes an iterative correction method based on raw event data.The proposed method requires no additional hardware support and directly calibrates the gain coefficients of each channel directly using event data acquired by the detector. Channel energy data are extracted for each event, and the total energy is computed to locate the photopeak position.An energy selection window is then applied to retain valid events, thereby suppressing the influence of scattered and noise events. On this basis, an iterative optimization process is employed to refine the gain coefficients of each channel, gradually converging the event energy distribution toward

the photopeak. The correction effect is assessed by the energy resolution derived from the resulting energy spectrum. Experimental results show that the proposed method effectively compensates for channel response inconsistencies, significantly improves detector performance including energy resolution, and consequently enhances imaging quality and accuracy. The method is simple to implement and highly practical, and can be directly integrated into the data processing pipeline of existing detection systems.

A Python-based Tool for Automated Geant4 Simulations of Scintillation Detectors (#2509)

Ayush Priyadarshi[1], Anil K. Gourishetty[1,2], Kavish Madhan[1], Virendra Ranga[2,1]

[1] Indian Institute of Technology, Roorkee, Department of Physics, Roorkee, India; [2] Tata Institute of Fundamental Research, Mumbai, Dept of Nuclear and Atomic Physics, Mumbai, India

I am grateful to G. Anil Gourishetty for this opportunity. I would also like to thank my parents, Capt. Arvind K. Prasad and Kumari Priyadarshini, along with my sister Ashika.

Abstract

This paper presents the development of a compact Geant4-Python simulation-analysis tool for a reproducible gamma response scintillation detector. The tool couples a configurable Geant4 C++ backend with Python automation for macro generation, simulation execution, ROOT-file validation, deposited-energy spectrum generation, count extraction and summarisation in a table. Unlike a general-purpose detector framework, the present implementation is focused on the end-to-end workflow required for scintillation detector response studies using solid cylindrical, hollow cylindrical, and near-4π soccerball-style geometries. Simulations with Cs-137 for 10^8 events demonstrate the complete workflow, while higher-statistics validation runs on PARAMGanga (Super-Computer at IITR) indicate that the same structure can be extended to larger detector-response campaigns. The resulting tool reduces manual intervention, improves traceability, and provides a reusable starting point for systematic Geant4-based gamma-spectroscopy simulations.

Development and deployment of a compact beta/gamma spectrometry chain for autonomous ground vehicles in nuclear decommissioning

(#2624)

Pierre-Louis Antonsanti[1], Julien Venara[1], Marie Cuozzo[1], Thibaud Durand[1], Jérémy Seyssaud[1], Matteo Pacini[3], Eric Cantrel[2]

[1] Université de Montpellier / CEA, DES/ISEC/DPME/SEIP/LNPA, Bagnols-sur-Cèze, France; [2] Université de Montpellier / CEA, DES/ISEC/DPME, Bagnols-sur-Cèze, France; [3] Sigma Ingegneria, Lucca, Italy

This work was supported in part by the European project XS ABILITY under Grant BS123456.

Abstract

The XS ABILITY project aims to deploy a swarm of autonomous unmanned ground/aerial vehicles equipped with advanced radiation detection technologies for Dismantling & Decommissioning operations. As part of this effort, we developed a compact beta/gamma spectrometry chain to monitor concrete surfaces potentially contaminated with ^{137}Cs or ^{90}Sr, the main fission products encountered in nuclear facilities. The detection system comprises a 4-mm-thick plastic scintillator coupled to a photomultiplier tube, optimized for ^{90}Sr/^{90}Y full beta energy deposition. Analog signal processing is performed using a wireless, portable multichannel analyzer (CAEN Gammastream), adapted to both payload constraints and real-time measurements. It is currently being integrated into the Sigma Rover for automated floor/wall measurements. Energy calibration and resolution were estimated in laboratory using standard sources (^{137}Cs, ^{207}Bi, ^{241}Am), complemented by an uncertainty analysis addressing calibration parameters, measurement geometry, and background noise. A Monte Carlo model of the spectrometer was developed and validated against experimental data, facilitating simulations of configurations infeasible in laboratory settings. One of the target test cases of XS Ability being the CEA Marcoule G2 reactor currently undergoing dismantlement, a campaign of automated background noise measurements in the building is scheduled. The analysis of the spatial variability of the signal and the accessibility of the facility are key steps in the development of robust and automated scans. The measures will complement the uncertainty analysis, thus improving the contamination detection and reducing the false alarm and false negative rates. Ongoing work focuses on developing machine-learning-based algorithms for source identification (^{137}Cs, ^{90}Sr) and localization, targeting both surface and subsurface contamination.

Neutron and secondary photon dose mapping of deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators via PHITS simulations (#2970)

Andrea G. Alipio[1], Christine L. Dulohan[1], Bernhard Egwolf[2], Alvie Asuncion-Astronomo[3]

[1] University of Santo Tomas, The Graduate School, Manila, Philippines; [2] University of Santo Tomas, Department of Mathematics and Physics, Manila, Philippines; [3] Department of Science and Technology, Philippine Nuclear Research Institute, Quezon City, Philippines

This work is supported by the DOST-PCIEERD-funded project NURAD Component 2: "Accelerator Driven Subcritical Nuclear Reactor" with Project Number 1211979.

Abstract

The Monte Carlo-based Particle Heavy Ion Transport Code System (PHITS) was used to model deuterium-deuterium (D-D) and deuterium-tritium (D-T) neutron generators for preliminary radiation safety assessment of the ongoing establishment of the Neutron Irradiation Facility (NIF) of the Philippine Nuclear Research Institute (PNRI). Neutron and secondary photon dose distributions were obtained for fully shielded, partially shielded, and unshielded configurations. In both D-D and D-T cases, the counting room dose rates were acceptable with respect to occupational dose limits for a 500-hour annual operating time. However, additional shielding should be explored for the D-T setup to further reduce dose rates in the work area. The dose maps presented the significance of the configuration of moderating and shielding materials in minimizing radiological doses during operation. The findings of this work will serve as a reference for the safe and reliable installation of the country's first neutron generator laboratory.

NSS-13-210

Count-Level Effects on Radiomics Robustness and Harmonization in Total-Body PET Imaging (#3090)

Mohamed Saber Azimi[5], Maryam Cheraghi[7], Habib Zaidi[1]

[1] Geneva University Hospital, Division of Nuclear Medicine & Molecular Imaging, Geneva, Switzerland; [2] Geneva University Hospital, Division of Nuclear Medicine & Molecular Imaging, Geneva, Switzerland; [3] Odense University Hospital, Deptartment of Nuclear Medicine, Odense, Denmark; [4] Odense University Hospital, Deptartment of Nuclear Medicine, Odense, Denmark; [5] Obuda University, University Research and Innovation Cente, Budapest, Hungary; [6] Obuda University, University Research and Innovation Cente, Budapest, Hungary; [7] Shahid Beheshti University, Department of Nuclear Medicin, Tehran, Iran; [8] Shahid Beheshti University, Department of Nuclear Medicin, Tehran, Iran

This study was financially supported by the Swiss National Science Foundation (SNSF, grant No. 30030–231742) and the Geneva League Against Cancer (grant No. LGC 2402).

Abstract

Radiomics analysis in total-body PET imaging is highly sensitive to acquisition variability, particularly count reduction, which directly affects noise characteristics and feature reliability. In this study, we investigate the impact of count reduction and multi-parametric harmonization on the robustness of multi-organ radiomics. A retrospective dataset of 550 patients from two centers was analyzed. Multiple count levels were generated from list-mode data, including standard and reduced counts (reduction factors up to 100). Multi-organ segmentation was performed automatically, and 107 IBSI-compliant radiomics features were extracted from SUV-normalized images. Feature harmonization was applied using ComBat under different configurations, including scanner, voxel size, radiopharmaceutical, and scatter correction. Reproducibility was evaluated using intraclass correlation coefficients across count levels and anatomical regions. Results show that radiomics stability is strongly dependent on both count level and feature type. Approximately 31% of features achieved good reproducibility (ICC ≥ 0.75) in at least one organ. Shape and first-order features remained relatively stable under moderate count reduction (CRF ≤ 20), while higher-order texture features exhibited substantial degradation at extreme count levels (CRF ≥ 50). Harmonization improved feature consistency, particularly for scanner- and resolution-related variations, but had limited impact under severe noise conditions. Taken together, the results indicate that preserving quantitative reliability in low-count PET requires careful consideration of both feature selection and acquisition variability. Rather than relying solely on harmonization, robust radiomics analysis should incorporate count-aware strategies, especially when extending to multi-center or ultra-low-count imaging scenarios.

A Geant4 add-on package to emulate surface electron response in Monte-Carlo simulation (#3237)

Georgios Konstantinou, Sara El Akel, Christophe Baillif, Nicolas Wyrsch

EPFL, PV Lab, Neuchatel, Switzerland

Abstract

One of the most complex aspects of understanding and simulating accurately micro-channel plate structures is the accurate estimation of surface response of electron impacts, an integral part of the avalanche driven multiplication process that dictates gain and temporal charge profiles. Electron behavior is heavily affected by the surface quality, roughness, material thickness, deposition process and other details that are difficult to model. For this reason, a lot of groups rely on measurements, which are then introduced in different simulators, such as COMSOL Multiphysics, SimIon or others. Geant4 is the state-of-the-art community-based Monte-Carlo simulation software. Several new physics packages have been introduced over the years to simulate low-energy electron interactions; however, it is very difficult to emulate the entirety of optimizations that can lead to accurate simulation. For this reason we develop an package that allows accurate electron response on surfaces by allowing import of experimental data and is calibrated through an emulation run. The purpose is not to substitute the scatter/back-scatter mechanism that is native to Geant4, but allow light-weight and accurate surface responses to be integrated in full MCP simulations, including multichannel and broad range primary kinetic energies. The model is benchmarked against a fully developed COMSOL model and experimental gain results and tried in various primary scenarios, including direct alpha, beta, beta+ and gamma absorption.

Multi-energy Radiography Using a Three-energy Accelerator and Dual-layer Detectors (#1028)

Zhusong Mei[1], Yongle Dang[1], Chunguang Zong[1,2], Yanwei Xu[1,2], Lei Liu[1,2], Bicheng Liu[1]

[1] Nuctech Company Limited, Beijing, China; [2] Tsinghua University, Department of Engineering Physics, Beijing, China

Abstract

Traditional dual-energy X-ray cargo inspection systems are limited in thin-material discrimination and detail visibility because low- and high-energy information is mixed within broad bremsstrahlung spectra. This work presents a multi-energy imaging system based on a 6/3/0.3 MeV three-energy accelerator and dual-layer detectors, enabling acquisition of six effective energy channels in a single scan. Experimental results show that the 0.3 MeV channel significantly improves detail resolution, achieving a wire resolution of 0.9 mm. A random forest classifier achieves

92% overall accuracy for four representative materials over a mass-thickness range of 1–120 g/cm2, outperforming a conventional dual-energy configuration by approximately 28%. These results demonstrate that the proposed architecture is a promising solution for high-precision cargo and vehicle inspection.

This work is based on the research supported wholly by National Research Foundation of South Africa (90741, 99037, 127116) and iThemba LABS.
Supported 2023-24 by the Technology Innovation Agency under Grant number 14606/01

Abstract
iThemba LABS has pioneered a mobile gamma-ray detection unit [1] which allows a user to operate in the field and chart the location, strength and energy of gamma radiation. The system incorporates a sensitive scintillation detector [2] typically used for accelerator-based spectroscopy at the SSC laboratory and was integrated into a backpack incorporating a fast 125 MHz digitiser for readout and a GPS enabled Raspberry Pi microprocessor system, allowing in situ measurements of radiation around the Cape Town site, with collected data streamed to the cloud and analysed offline. The Portable African Neutron-Gamma Laboratory for Innovative Nuclear Science (PANGoLINS) project [3] aims to investigate measurements of both gamma rays and neutrons which forms an important component part on site or in transit and the detection of both fissile material for the use in decarbonised energy sources or disposal thereof. A core component of the project is be to miniaturize the weight of the gamma-ray detection device and associated infrastructure so that it can be loaded on an uncrewed aerial vehicle to enable access to, and enhance performance of radiation monitoring measurements at remote sites leading to autonomous operations. PANGoLINS incorporates commercial detector assemblies of $LaBr_3$(Ce), SrI_2(Eu) and/or CLYC(Ce) for spectroscopy. In addition, the project encompasses the instrumentation of other scintillation detectors with silicon photomultiplier technologies. The coupling of these to readout devices such as high-density ADC readout are planned for applications for nuclear science, medical imaging or astronomy.

Feasibility Study on Ghost Imaging-based Neutron Depth Profiling for 3D Lithium Distribution Mapping (#1125)

Junhyeok Kim, Jinhwan Kim

Korea Atomic Energy Research Institute, DAEJEON, South Korea

This research was supported by the Korea government (MSIT) (1711078081) and by the National Research Council of Science & Technology (NST) grant by the Korea government (MSIT) (No. CAP25031-000).

Abstract

This paper investigates the feasibility of three-dimensional lithium distribution mapping in solid-state electrolytes by integrating ghost imaging with neutron depth profiling. In the proposed system, a cold neutron beam is spatially modulated by a sequence of 32×32 Hadamard-patterned cadmium masks, and a single-pixel charged-particle detector records the energy spectrum for each pattern. Since each energy bin corresponds to a specific depth layer via the stopping power, reconstructing a lateral image independently for every energy bin and stacking them along the depth axis produces a complete three-dimensional lithium map without mechanical scanning. Monte Carlo simulations were performed with 1024 mask patterns and 5×10^8 neutron histories per pattern. Images were reconstructed using an untrained neural network-based algorithm at sampling ratios of 25%, 50%, 75%, and 100%. At 100% sampling, the peak signal-to-noise ratio and structural similarity index reached 7.5 dB and 0.577, respectively. Although these quantitative scores remain modest due to limited source statistics, the reconstructed images qualitatively resolve the target lithium-rich structures across all depth layers. Compared to conventional pinhole-scanning approaches that require exhaustive spatial sampling, the proposed method would achieve comparable image quality at 50% sampling, directly halving beam time and making three-dimensional characterization practically feasible.

Feasibility Study of Thermal-Neutron Localization Using a GAGG-Based Directional Probe (#1183)

Yuhang Qiu[1], Tiantian Dai[2], Qingyang Wei[1]

[1] University of Science and Technology Beijing, School of Automation and Electrical Engineering, Beijing, China; [2] China-Japan Friendship Hospital, Department of Radiation Oncology, Beijing, China

This work was supported by Project “Vice President of Science and Technology” of Changping District, Beijing (Grant No. 202503003030).

Abstract

This work evaluated the feasibility of thermal-neutron localization using a directional probe originally developed for gamma-ray source localization. The probe consisted of 30 GAGG scintillator bars surrounding a tungsten cylinder and was modeled by Monte Carlo simulation. Thermal neutrons were generated from a ^{252}Cf point source placed at the center of a spherical high-density polyethylene moderator. Localization was performed using a centroid vector method based on events recorded within the energy window around the characteristic 80 keV capture-related peak. Ten source directions at a source-to-detector distance of 0.5 m were evaluated under ideal noise-free conditions. Representative results showed the localization accuracy improved as the number of valid counts in the selected energy window increased. The mean angular bias decreased from 4.12° at 100 valid counts to 0.78° at 2700 valid counts, demonstrating sub-degree average localization accuracy at higher count levels. These results support the feasibility of thermal-neutron localization with a compact GAGG-based directional probe and suggest potential future use in simultaneous neutron and gamma-ray localization for nuclear security applications.

Abstract

Spent Nuclear Fuel (SNF) contains various radionuclides and emits significant levels of radiation; therefore, accurate and effective inspection methods for identifying partial defects within SNF are essential. In our previous study, we proposed and fabricated a scintillator-based Gamma Emission Tomography (GET) system named the Yonsei Single-photon Emission Computed Tomography (YSECT). The purpose of this study is to experimentally evaluate the its performance and applicability under conditions mimicking actual inspection conditions. The YSECT system consists of four detection modules, a data acquisition module, a Peltier-based cooling system, and a rotation module. For employing the YSECT instrument to partial-defect inspection, a waterproof test was conducted at a depth of 1.58 m for 120 minutes. In addition, the performance and applicability of the YSECT instrument were evaluated by acquiring projection and tomographic images. The waterproof test confirmed that water intrusion was not assessed into the instrument. While a comparison of projection images obtained in air and water revealed some degradation in image quality—specifically regarding noise levels and spatial resolution—and an exponential decrease in pixel intensities in the inner layers due to water attenuation and lead dummy pins, the source distribution remained clearly distinguishable across the entire SNF region. These results demonstrate that the YSECT instrument is highly effective for detecting partial defects in SNF. Future studies will focus on validating the system under actual SNF inspection conditions.

Abstract

The time-emission profile of delayed neutrons (DNs) emitted by decaying fission fragments and induced by an external, time-modulated interrogating source can be used to identify the isotopic composition of uranium samples. In low- and high-enriched samples, a single isotope dominates the DN temporal profile, complicating measurements of isotopic composition. By suitably moderating the neutron spectrum of an interrogating neutron source, the large thermal fission cross-section of ^{235}U can be leveraged to amplify its signal, thereby improving the ability to measure lower enrichments. This work evaluates the use of neutron moderation in DN-based enrichment measurements using a Monte Carlo simulation. The ^{235}U-to-^{238}U fission ratio serves as the optimization metric, since DN production is proportional to the number of fissions. Optimal moderating configurations that yield a near-unity ^{235}U to ^{238}U DN emission ratio for low-enriched and high-assay low-enriched uranium were determined. Based on this analysis, an experimental design has been developed for future validation. DN temporal analysis offers the prospect of nondestructive uranium assay across the entire ^{235}U enrichment range, from depleted (0.3% ^{235}U) to highly enriched (93.0% ^{235}U) uranium.

Improving contraband thermal neutron capture gamma detection in low and medium-Z cargo with pulsed D-T active neutron interrogation

(#1300)

Ketaki Joshi, Xianfei Wen, Jason P. Hayward

University of Tennessee, Department of Nuclear Engineering, Knoxville, USA

This material is based upon the work supported by the Department of Homeland Security and the Department of Energy National Nuclear Security Administration through Defense Nuclear Nonproliferation's Enabling Capabilities in Technology Consortium under the award numbers 21CWDARI00041-01-00 and DE-NA0004197.

Abstract

Identification of shielded contraband like chemical weapons, explosives, and drugs being illegally transported in cargo containers can be achieved by detecting gamma rays produced using active pulsed D-T neutron interrogation. The time-dependent active gamma background produced by various low to medium-Z benign cargo-filling materials can interfere with contraband gammas and can make rapid and reliable detection of such contraband challenging. Using optimized timing gates depending on cargo-type for gamma spectra analysis can improve the signal-background ratio of contraband gammas. In this work we use a 6x6 array of 3"x8" NaI(Tl) detectors with coincidence-summing addback for full energy peak reconstruction and a pulsed D-T neutron generator to understand the gamma background produced by empty cargo, and paper and steel cargo filled to 0.6 g/cc density in our cargo inspection setup. We identify optimized timing windows for each cargo and validate the optimization with d_a signal sensitivity calculations.

Abstract
The detection of water in a mock advanced gas reactor slotted can has been carried out using non-radioactive surrogate materials. The method of detecting water is via prompt gamma activation analysis of hydrogen. This results in a prompt 2.223 MeV γ-ray. Due to the absence of hydrogenous materials in the fuel matrix, the 2.223 MeV γ-ray is indicative of the presence of water. GEANT4 simulations of the mock slotted can have demonstrated the variation in 2.223 MeV γ-ray intensity dependent on the location of water. High density polyethylene blocks equivalent to and above water mass detection limits set out in literature were exposed to ^{252}Cf sources. The γ spectra obtained were examined.

This work was supported by JAEA Nuclear Energy S&T and Human Resource Development Project Grant Number JPJA25P 25135771.

Abstract
A compact handheld alpha–beta radiation detector was developed for field applications in nuclear decommissioning environments. At decommissioning sites such as the Fukushima Daiichi Nuclear Power Plant, mixed contamination from alpha- and beta-emitting radionuclides requires rapid and reliable on-site radiation measurements. To address these challenges, the developed detector enables real-time alpha–beta discrimination

while maintaining compact size, lightweight design, and battery-powered operation. The detector employs a Ce-doped Gd 2Si2O7 (GPS) scintillator coupled with a Multi-Pixel Photon Counter (MPPC). Signal processing and radiation discrimination were performed using an FPGA, and the measured count rates and energy spectra were displayed in real time on an LCD via a Raspberry Pi Pico microcontroller. The device weighs approximately 1.3 kg and can operate continuously for up to 8 hours on battery power. Pulse height spectra showed a speak for alpha particles, while beta particles exhibited continuous spectra. The detector achieved a detection efficiency of 90.7% under the measurement conditions. By applying a low-energy threshold (LLD) at channel 190, more than 80% of the alpha counts were retained, whereas the beta counts were reduced to 6.4%, demonstrating effective alpha–beta discrimination. Real-time measurement results, including count rates and spectra, were successfully displayed on the LCD screen. These results demonstrate that the developed handheld detector provides effective alpha–beta discrimination and is suitable for rapid, on-site radiation measurements in mixed contamination environments encountered during nuclear decommissioning activities.

Abstract

We report a proof-of-concept pulsed neutron de- tection experiment using SOFIST3, a silicon-on-insulator (SOI) pixel detector with per-pixel energy and timestamp recording. SOFIST3 was tested at the NOBORU beamline (BL-10) of J-PARC/MLF using a ^{10}B conversion layer. Two-dimensional spatial distributions of charge signal and timestamp were recorded, confirming simultaneous per-pixel energy and timing measurement under neutron irradiation. The pixel occupancy increased proportionally with beam intensity—from approximately 1.7×10^4 to 5.1×10^4 hits/cm^2/s over a factor of ~3 in intensity—demonstrating count rate performance free from the system-wide dead time that limits conventional SOI pixel detectors. These results provide a foundation for developing dedicated high count rate neutron imaging detectors based on SOI pixel technology.

Experimental and Simulation Studies of FFCC Measurements Using a D-D Neutron Generator (#1563)

Makoto Maeda, Masao Komeda, Yosuke Toh

Japan Atomic Energy Agency, Nuclear Science and Engineering Center, Tokai-mura, Japan

This work supported by the Decommissioning, Contaminated Water and Treated Water Management Project funded by the Ministry of Economy, Trade and Industry (METI), Japan.

Abstract

Quantification of nuclear material in fuel debris at the Fukushima Daiichi Nuclear Power Station is expected to contribute to the streamlining of processing and management. The Fast Fission neutron Coincidence Counting (FFCC) method has been proposed as a non-destructive assay technique that utilizes fast neutrons, which are less affected by neutron absorbers contained in the debris. In FFCC measurements, an external neutron source is used to induce fission. Compared with conventional D-T systems, D-D neutron generators are more suitable for on-site deployment due to the absence of tritium and the lower neutron energy, which reduces shielding requirements. However, their lower neutron yield and smaller fission cross-sections pose challenges for measurement. In this study, the feasibility of FFCC measurements using a D-D neutron generator was experimentally demonstrated with EJ-301 liquid scintillation detectors. Time-difference spectra were obtained from uranium samples with and without B_4C neutron absorbers. Clear coincidence peaks were observed in both cases, indicating that fission neutrons can be successfully detected even in the presence of neutron absorbers, with less than a 10% reduction in counts. In addition, Monte Carlo simulations were performed using a designed measurement system to evaluate the feasibility of measurements within a practical measurement time. The results indicate that sufficient counting statistics can be obtained. These results demonstrate the feasibility of the FFCC method using a D-D neutron generator and its potential applicability to the non-destructive assay of fuel debris.

Compact and modular ^{6}LiF:ZnS(Ag) neutron detectors (#1609)

Felix Liang, Adam Esquibel, Nicholas Floyd, Heshani Jayatissa

Los Alamos National Laboratory, ISR Division, Los Alamos, USA

Los Alamos National Laboratory is managed by Triad National Security, LLC for the U.S. Department of Energy's NNSA.

Abstract

Neutron detection plays an important role in nuclear security, industrial applications, space exploration, and basic science research. Some compact neutron detectors made with ^{6}LiF:ZnS(Ag) and wavelength shifters have been deployed in portable instruments for nuclear security. In such detectors where photosensors are attached to one end of the wavelength shifter, high photon propagation efficiency for the wavelength shifter is required so that the signal-to-noise ratio of the photosensor is adequate for signal processing. Monte Carlo simulations using Geant4 were performed to study photon propagation efficiency for wavelength shifter panels and bars. Compact neutron detector modules were constructed according to the results of the Geant4 simulations. An initial test using a ^{252}Cf source shows the 10x10x45 mm^3 bar detects more neutrons than the 10x10x30 mm^3 bar and a majority of events have a small pulse height resulting from neutrons detected further away from the photodiodes. Although the count rate of the 45 mm bar for HDPE moderated neutrons was 67% lower than a 10 atm ^{3}He tube, its length is 3 times shorter than the ^{3}He tube.

Abstract

Accurate quantification of radon (^{222}Rn) exhalation rate from consumer products containing naturally occurring radioactive materials (NORM) is essential for source-term-based safety evaluation. This requires a sealed measurement chamber whose tightness and internal radon concentration homogeneity are characterized to ensure data integrity. We characterize a 0.343 m³ stainless-steel radon chamber housing two Durridge RAD7 alpha spectrometers for low-emanation NORM measurements. Chamber tightness, evaluated via the radon decay curve method over ~24 days, yielded a fitted leak rate constant statistically consistent with zero (1σ uncertainty 1.7×10^{-5} h^{-1}), more than an order of magnitude below the 5 % × λ_{Rn} acceptance criterion. To support spatial homogeneity evaluation, a MATLAB advection–diffusion solver with a real Navier–Stokes velocity field (Chorin projection method) was developed as a transferable computational framework, deliberately trading full turbulence-model fidelity for accessibility. Preliminary simulations indicate that fan-driven advection (2.0 m/s) reduces the spatial coefficient of variation (CV) below the 5 % target within ~10^1 arbitrary time units, approximately three orders of magnitude faster than under natural diffusion alone (~10^4 a.u.). Experimental cross-validation using a calibrated Pylon ^{226}Ra source and two RAD7 units in a crossover configuration is in progress and will be presented at the conference. This integrated experimental and computational protocol qualifies the chamber for high-precision radon exhalation measurements of NORM products, enabling consistent and conservative safety regulation.

Abstract

Cultural heritage preservation requires non-invasive in-situ detection techniques to avoid irreversible damage to fragile relics. Compton scattering imaging (CSI), based on single-sided backscattering detection, offers a promising alternative to X-ray transmission imaging for nondestructive testing (NDT) at archaeological sites. This paper presents two push-broom CSI systems for on-site in-situ NDT of cultural heritage. A modified 2D CSI system was deployed at an auxiliary pit in Xi'an, effectively revealing shallow subsurface burial features and locating unexcavated relics. A 3D Compton scattering tomography system was further developed to address depth limitations, featuring a soil penetration depth of over 10 cm and a spatial resolution of 1cm with preliminary experiments verifying its technical feasibility for 3D structural characterization of buried artifacts.

Abstract

The prompt detection of marine environmental radioactivity is essential in the wake of accidents such as the Fukushima event, yet conventional methods relying on bulk seawater sampling and offline analysis cannot provide timely information. We developed an in-situ underwater gamma-ray monitoring system, operable down to 300 m depth, that integrates real-time cesium preconcentration with a low-background gamma-ray spectrometer for deployment on unmanned surface vehicles, underwater gliders, and mooring platforms. The 18.54 kg system

houses a seawater circulator, a pressure regulator, a dual-head gamma-ray detector, and a battery within a 58 cm × 21.4 cm watertight enclosure. Each detector head consists of a 2×2 tiled array of 48×48×20 mm³ monolithic GAGG:Ce crystals (96×96 mm² active area) coupled to a 16×16 SiPM array, with a KNiFC resin column placed between the opposing heads for selective ^{137}Cs adsorption. KNiFC-based preconcentration yielded over 92% ^{137}Cs recovery from spiked seawater. In a 30-bar pressure chamber, the system operated stably for 1 hour, and underwater background counts in the 662 keV region were reduced by a factor of 17 owing to water shielding. Under this low-background condition, two ^{137}Cs-preloaded adsorbent columns containing as low as 11.4 mBq and 73.2 mBq were observable within the 662 keV photopeak window, with net counts scaling consistently with the loaded activities. With a photopeak detection efficiency of 0.13, the system achieved a minimum detectable activity of 5.8 mBq/L for a 60 L sample within a 1-hour measurement, demonstrating sub-10 mBq/L sensitivity for in-situ ^{137}Cs detection in deep-sea environments.

Vehicle Based Detection System for Gamma-Neutron Background Measurements (#2083)

Luke G. Morris, Tom Crane, Maxim B. Joseph, Matt P. Taggart

AWE Nuclear Security Technologies, Reading, UK

Abstract

The variability of background radiation, primarily gamma rays and neutrons, can have a significant impact on the performance of detector systems. In nuclear security, background-limited minimal detectable activity constrains which sources can be detected with acceptable confidence. Furthermore, the radiation background can have direct impact on the false alarm rate; higher background levels can lead to increased false alarm rates, normally mitigated by increasing thresholds, which decreases the system sensitivity. The local environment is one of the main factors in background rate variation. Therefore, a vehicle-based system is a well-suited detector platform to investigate dynamically changing environments. This work summarises the design and creation of a custom vehicle-based system assembled at AWE-NST as a platform for experimental gamma and neutron background measurements. This platform can also be used to benchmark novel anomaly detection algorithms. This work details the results from the first measurement campaign taken in July 2025 with the system driven over 247 miles around the counties of Hampshire and Berkshire in the UK.

Performance Evaluation of a Portable MMXRF for Safeguards Environmental Sample Analysis under Transport-induced Alignment Changes (#2222)

Sung-Woo Kwak[1], Woojin Kim[1], Jinho Ryu[1], Juwan Kang[2], Yong Hyun Chung[2]

[1] Korea Institute of Nuclear Nonproliferation and Control, Safeguard Division, Daejeon, South Korea; [2] Yonsei University, Department of Radiation Convergence Engineering, Wonju, South Korea

This work was supported by the Nuclear Safety Research Program through the Korea Foundation Of Nuclear Safety(KoFONS) using financial resources granted by the Nuclear Safety and Security Commission (NSSC) of the Republic of Korea (RS-2021-KN063810).

Abstract

The Korea Institute of Nuclear Nonproliferation and Control (KINAC) has developed a portable Monochromatic Micro X-Ray Fluorescence (MMXRF) analyzer. This device is designed for the on-site measurement and evaluation of safeguards environmental samples to rapidly identify and respond to undeclared nuclear activities. Due to its portable nature for field inspections, the equipment is frequently subject to transportation. This movement can lead to misalignments between critical components which must remain precisely fixed for optimal performance. In this study, we conducted experiments to evaluate how transportation-induced alignment errors and environmental background noise affect the device's performance. The MMXRF system was transported from KINAC to two places. We measured the shift in the X-ray focal spot and background noise before and after each transit. Experimental results indicated a focal spot displacement of approximately 1.7 mm following transportation. While background noise levels remained relatively stable, significant performance degradation was observed during measurements of uranium-deposited swipe standard samples. These findings suggest that the shift in the X-ray focal spot is a primary driver of performance loss. In conclusion, this study confirms that the alignment stability of the X-ray generator is a critical factor in maintaining the reliability of portable safeguards equipment. We will discuss detailed methodologies and technical solutions to mitigate these alignment issues at the conference to ensure the high-fidelity performance of portable MMXRF systems in the field.

NSS-13-248

Measurement of 3-dimentional Distribution of ^{60}Co in a Graphite Block by Three Pinhole Gamma Cameras (#2268)

Jun Kawarabayashi, Yusuke Takabayashi, Naoto Hagura

Tokyo City University, Department of Nuclear Safty Engineering, Setagaya-ku, Japan

Abstract

Cobalt-60 isotopes are sometimes detected in graphite blocks used in research reactors with small cores. One possible cause of this cobalt-60 is the activation of impurities within the graphite blocks by neutrons. Another possible cause is the activation of rust adhering to the surface of the graphite blocks. When disposing of these graphite blocks, the distribution of radioactive materials measured by non-destructive methods would greatly contribute to improving the accuracy of radioactive material quantification. Therefore, we prototyped simple gamma camera combining a pinhole collimator and a phosphor plate. Using this camera, we imaged the block from three directions and attempted to measure the three-dimensional distribution of radioactive materials based on the acquired data. We prepared the detector response function in advance through Monte Carlo simulation. Images were captured by the gamma camera experimentally with a PLA resin block embedded with a cobalt-60 source and estimated the position of the source using ML-EM algorithm. From these results, when the source was placed at the corner of the block, the location of the source was estimated in the correct position. On the other hand, when the source was placed at the center, it was estimated to be at an adjacent position. Improving the accuracy of the response function is the next step of this study.

NSS-13-250

Verification of the Outer Space Treaty with trapped Protons in the VanAllen Radiation belt (#2270)

Areg Danagoulian

Massachusetts Institute of Technology, Nuclear Science and Engineering, CAMBRIDGE, USA

See https://arxiv.org/abs/2512.20016 for full a list of acknowledgements.

Abstract

The Outer Space Treaty (OST), opened for signature in 1967 and ratified by 117 countries including the U.S., Russia, and China, prohibits the placement of nuclear weapons in outer space. The OST, however, lacks any verification mechanism, and no peer-reviewed methodology for verification has been proposed in the open literature. Recent concerns over Russia's Kosmos2553, suspected of testing nuclear-armed anti-satellite (ASAT)

components, and a U.S. executive order calling for the detection of nuclear weapons in space, have made the need for a credible verification capability urgent. A nuclear detonation in Low Earth Orbit (LEO) could destroy most LEO satellites, as the 1962 Starfish Prime test demonstrated. This study presents a concept and feasibility analysis for verifying a satellite's compliance with the OST by detecting neutrons induced by proton spallation on the thermonuclear device's high-Z (uranium) radiation case. The interrogating GeV-energy protons are naturally provided by the inner Van Allen belt, requiring no active source. The proposed inspector is a 9U-CubeSat-sized directional neutron detector consisting of two 30x30 pixel planes, with each pixel formed by an EJ-276 PSD plastic scintillator wrapped in CVD-diamond active vetoes. Geant4 simulations characterize anti-coincidence rejection of the harsh proton/electron environment, directional discrimination of spallation neutrons from atmospheric albedo neutrons via neutron-scatter-camera kinematic reconstruction, and dead-time effects due to the high charged-particle flux. Combined with IRENE AP9/AE9 belt models and Carpenter's spallation yield, the analysis shows that the 9U inspector can confirm the presence of a thermonuclear weapon from a stand-off of 4 km in approximately one week, with a false-positive rate <1.1%. A constellation of ten inspectors at 1 km reduces this to a single-flyby inspection.

NSS-13-252

Optimization of Detector Configuration for Enhanced Neutron Imaging Reconstruction Accuracy in Tokamak Fusion Reactor (#2283)

Gyeongjin Choi, Beomkyu Kwon, Ill-Hyuk Han, Kyoung-Jae Chung

Department of Energy System Engineering, Seoul National University, Seoul, South Korea

This work was supported by the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (RS-2023-00281276) of the Republic of Korea.

Abstract

This study investigated the quantitative effects of neutron camera configuration with various parameter—the number of channels, colimator window diameter, and channel allocation for each port—on imaging performance in Deuterium-Tritium (DT) fusion reactor environments. Plasma neutron emission profiles were generated using the TRIASSIC code, which generating plasma shape, and detector signals were calculated in both 2-D and MCNP-based 3-D environments. Neutron image reconstruction was performed using the calculated detector signals, and reconstruction accuracy was evaluated using the Normalized Mean Square Error (NMSE). First, neutron image reconstruction was performed using the reference neutron camera configuration proposed for ITER and EURO-DEMO, resulting in an NMSE of 3.12%. To improve reconstruction accuracy, an expanded neutron camera configuration consisting of 10 and 16 channels for each vertical and radial neutron camera(VNC and RNC) port, respectively, was applied. The reconstructed results yielded NMSE values of 1.59% in the 2-D and 1.85% in the 3-D environment, both lower than the reference value. Reconstruction accuracy was strongly affected not only by the total number of detector channels but also by the channel distribution and Line-of-Sight (LoS) coverage. In particular, asymmetric detector distributions in the VNC ports generally produced lower NMSE values than symmetric configurations, while increasing the detector channel number in the RNC port improved reconstruction

accuracy overall. These results indicate that appropriate neutron camera configuration can enhance neutron imaging performance in DT fusion reactor environments and may provide fundamental data for future neutron camera design and optimization for DEMO-class fusion reactors.

Characterization of Floating Gate Dosimeter Structures through a Standardized FPGA-Based Radiation-Test Platform (#2338)

Evgenia Leonida[1,2], Salvatore Fiore[2], Antonio Scialdone[2], Salvatore Danzeca[2], Frederic Wrobel[1], Jerome Boch[1]

[1] University of Montpellier, IES - Institute of Electronics and Systems, Montpellier, France; [2] CERN, BE-CEM-EPR, Geneva, Switzerland

Abstract
Floating-gate dosimeters (FGDOS) are being investigated at CERN as candidates for the next generation of Total Ionizing Dose monitoring devices in the accelerator complex. This work presents the characterization of floating-gate dosimeter structures through a standardized CERN BE-CEM-EPR radiation-test platform using a common carrier board, dedicated sensor daughterboards with standardized pinout, and a Pynq FPGA readout implementing reusable gateware libraries and continuous-integration firmware validation. The platform allows the same device under test to transition from laboratory bring-up to irradiation facilities without setup modifications. The sensor is fabricated in a 0.6 µm CMOS process and exploits a digital control component — handling structure selection, bias control, charge injection, and frequency readout — combined with analog floating-gate NMOS structures, each paired with a matched dummy reference transistor for differential read-out. Two structures with different floating-

gate area to NMOS readout transistor ratios were characterized: a reduced-area variant at one quarter of the baseline retaining the same NMOS (TC994), and a variant with larger sensor area and optimized NMOS for lower noise (TC994). Four recharge modes were compared: disabled, comparator-based, counter-based, and bit-based. Temperature dependence of the sensor frequency was observed and used to validate the acquisition chain; sensor-to- reference frequency ratios were evaluated as a first-order thermal compensation method. The platform is being extended to a new generation of structures integrating normal NMOS, high-voltage NMOS, and parasitic NMOS readout implementations (TC994), whose laboratory and irradiation results will be presented with emphasis on suitability for future RadMon and BatMon Total Ionizing Dose monitoring at CERN.

Physics-Informed Response Matrix Optimization for Neutron Flux Unfolding (#2476)

Kilyoung Ko, Wonku Kim, Jongbum Kim, Kibeak Shin, Jinjoo Kim, Sunjin Kim, Jin Kim, Gujin Kang, Jintae Hong

Korea Atomic Eneregy Research Institute, Radioisotope Research Division, Daejeon, South Korea

This work was supported by Korea Research Institute for defense Technology planning and advancement (KRIT) grant funded by the Korea 310 government (DAPA, Defense Acquisition Program Administration) (22-107-C00-007) (JRIT-CT-23-055)

Abstract
Accurate characterization of neutron fields is crucial in applications involving neutron-emitting radioisotopes, as surrounding materials can alter these energy distributions. This necessitates a detailed reconstruction of neutron flux distributions beyond just dose-rate measurements. Reliable neutron flux reconstruction using compact organic scintillation detectors remains challenging under spectrally modified neutron fields owing to nonlinear light yield and detector resolution effects. In this study, we investigated the robustness of neutron flux unfolding using a stilbene scintillation detector with response matrices optimized using a physics-informed genetic algorithm (GA) framework. Although local differences in the unfolded flux distributions were observed under source-or neutron field–

mismatched conditions, the overall spectral shapes remained stable. The approach aids neutron flux reconstruction for various safety and evaluation applications. It enhances assessments in mixed radiation fields and nuclear environments.

This work is partially supported by the REALPATH project.

Abstract
In recent years, increasing attention in nuclear and medical applications has focused on detectors capable of neutron–gamma discrimination, with Pulse Shape Discrimination (PSD) being one of the most widely used and versatile techniques. A compact real-time detector has been previously developed, providing an event-by-event digital PSD parameter and a flexible platform for both organic and inorganic scintillators, as demonstrated using the CLYC crystal and, more recently, the M-700 scintillator. The system is based on a scintillator coupled to NUV-HD SiPM arrays and compact front-end electronics enabling real-time acquisition and processing. The detector achieves moderate Figures of Merit (FOM) while ensuring reliable neutron–gamma separation. To investigate the factors limiting its performance, an analytical model of the full detection chain was developed, including scintillator–SiPM coupling, readout electronics, and the main noise contributions (electronic noise, statistical fluctuations, time jitter, amplitude walk, and finite bandwidth-induced shaping in the analog chain). This framework allows the decoupling and quantitative evaluation of the effects limiting discrimination accuracy. Preliminary results show good

agreement with experimental data and identify the dominant limiting factors, providing guidance for targeted improvements and further performance enhancement.

Blade Checker – Radioisotope-free Positron Generator coupled with HPGe-based Doppler Broadening Spectroscopy for aircraft components maintenance operation (#2689)

Michael Ginsz[1], **Damian Ralet**[1], Jean-Michel Rey[2]

[1] MIRION Technologies, Lingolsheim, France; [2] POSITHOT, Villebon sur Yvette, France

Abstract
Accessing an early stage of damage evolution is a key factor for the aircraft industry. Positron annihilation allows very accurate and nondestructive measurement of defect density, and its future evolution, as probed by Doppler Broadening Spectroscopy. Once the limited availability of positrons is addressed using a nonradioactive positron generator, application of positron annihilation can be foreseen for maintenance activity addressing the aircraft industry.
The Blade Checker project is a proof of concept to demonstrate this capability. Although Blade Checker is focusing on the aircraft industry, this technique could be extended to other fields. It consists of a novel accelerator-based, radioisotope-free positron generator, custom HPGe detectors and an experimental setup allowing the defect density measurement on mechanical parts up to 3 dm^3.
The AM Gen is an accelerator-based positron generator, developed by POSITHOT, with a compact design and including the Xray shielding. Complemented by a beam stretching device, it provides a continuous positron flux of approximately 5.10^6 positrons per second. The generator has been commissioned by the French nuclear safety authority.
The signals coming from the positron annihilation require the resolving power of a High Purity Germanium (HPGe) detector focusing on the 511 keV peak shape analysis. MIRION Technologies developed a custom, 7-element, electrically cooled HPGe detector placed inside a vacuum chamber as close as possible to the sample to be measured. Several small elements are preferred over one large crystal to avoid pile-up effects. A time-listed multi-channel data-acquisition is used to have in-beam time correlation and coincidence.
A description of the systems, positron generator, HPGe system and readout, together with some results from material characterization and projected probing speed will be presented.

NSS-13-264

Optimization of the neutron source size for compensated neutron well logging (#2703)

Yu Xiang Liu, Yigang Yang

Tsinghua University, Department of Engineering Physics, Beijing, China

Abstract

Compensated neutron logging commonly employs isotopic neutron sources based on (α,n) reactions, such as Am–Be sources, which are typically approximated as point sources due to their small physical dimensions. However, alternative neutron sources based on (γ,n) reactions may require significantly larger target volumes to achieve sufficient neutron yield, making the point-source approximation no longer applicable. In this work, Monte Carlo simulations based on MCNP are performed to investigate the effect of neutron source length on compensated neutron logging response. A limestone–water formation model and a dual-detector configuration with near and far He-3 detectors are employed. The results show that the porosity sensitivity initially increases with source length, reaches a maximum at approximately 20 cm, and then gradually decreases. A figure-of-merit (FOM) combining sensitivity and statistical stability is further introduced, which increases monotonically with source length while gradually approaching saturation. The results provide a quantitative basis for neutron source optimization in compensated neutron logging.

NSS-13-266

Three-Dimensional Radiation Source Reconstruction with a Compound-Eye Compton Camera Using a NeRF-Inspired Neural Field (#2721)

Wenjie Yu, Minghao Dong, Yongshun Xiao

tsinghua university, beijing, China

Abstract

Compton cameras (CCs) have a large field of view and a wide energy detection range, and are useful in nuclear security monitoring, environmental radiation measurement, nuclear accident response, and radiation source localization. However, their depth accuracy is still limited in practical three-dimensional source localization. A single detector view provides weak spatial constraints, so traditional Compton reconstruction methods can produce depth errors, especially with few events, strong noise, or distant sources. Artifacts may also appear in the reconstructed images. To address this problem, we propose a three-dimensional radiation source reconstruction method for a compound-eye Compton camera based on a NeRF neural network structure. The aim is to improve localization accuracy by combining the compound-eye geometry with neural field learning. We simulated a compound-eye

detector system with 25 scatterers arranged on a spherical surface and absorbers arranged in a plane. For each detector view, list-mode Compton event data were used to perform independent MLEM reconstruction, and a source distribution image was obtained. These reconstructed images and the corresponding detector pose information were then used as training data for the neural field network. Preliminary results show that, after training with multi-detector data, the reconstructed three-dimensional radiation intensity distribution becomes more concentrated. The peak intensity position is closer to the true source position, and the depth shift is reduced. These results show that multi-detector geometric constraints can provide useful information for three-dimensional radiation source reconstruction, and that combining a compound-eye Compton camera with neural field reconstruction is feasible.

Abstract
The European Spallation Source (ESS), expected to start its scientific program in 2027, will be the world's most powerful neutron source. This facility requires advanced systems for accurate beam monitoring and diagnostics. To meet these requirements, dedicated detectors have been designed to operate at ESS, one of them being the Ionization chamber Beam Monitor (I-BM). This work presents detailed simulation studies, using Geant4, Garfield++ and LTspice, to investigate energy deposition, charge transport, induced current formation, and front-end electronics response. Experimental data from neutron beam test campaigns are also included to support the evaluation of the I-BM performance.

The authors thank the participating nuclear power plant staff and project team members for their support during laboratory tests, field measurements and digital-system integration.

Abstract

Fast, spatially complete and digitally usable radiation information is essential for radiation protection in nuclear power plants (NPPs), particularly during maintenance, decommissioning and emergency response. Conventional surveys usually separate geometric measurement from dose-rate measurement, which makes data acquisition slow, labor-intensive and difficult to integrate with digital radiation-protection platforms. This paper presents an indoor three-dimensional (3D) gamma radiation mapping method based on visual simultaneous localization and mapping (VSLAM). The developed DoseMap system combines an RGB-D VSLAM module with a hot-pluggable Geiger--Muller gamma dose-rate detector. Environmental point clouds, measurement trajectories and gamma dose-rate data are fused through timestamp synchronization and an integral path midpoint method, enabling real-time 3D visualization, radiation-field interpolation and hotspot localization. Tests in laboratories and NPP environments show that more than 80\% of the reconstructed scene point cloud is within 0.2 m of the reference cloud, the trajectory localization error is approximately 4 cm, the single-source hotspot localization error is less than 0.2 m, and measurement efficiency is improved by a factor of 26.8 compared with traditional survey workflows. The method has also been linked with the smart radiation-protection support system(SMARP), demonstrating its potential for digital twins, ALARA planning and remote or robotic radiation surveys.

Photofission Prompt Neutron Measurements from Active Photon Interrogation of Depleted Uranium with a Superheated Droplet Detector

(#2913)

Johann Piekar, Jeanne Vinoy, Vesna Simic, Adrien Sari

Université Paris - Saclay, CEA, LIST, F - 91120, Palaiseau, France

Abstract

Illicit transport of uranium-bearing materials remains a concern for nuclear security when passive radiation signatures are weak, shielded, or ambiguous. Active photon interrogation can induce photofission in uranium using a Bremsstrahlung field generated by 9 MeV electrons and provide neutron signatures from this reaction. Established photofission approaches commonly exploit delayed neutrons or delayed gamma rays measured after irradiation or in beam-off windows, which helps reject prompt radiation fields but imposes constraints on timing, sufficient decay statistics, and acquisition duration. Here, we propose a proof-of-concept measurement of prompt photofission neutrons using a depleted uranium bar and a commercial superheated droplet detector. Such passive neutron sensors rely on nuclear recoils that form bubbles when local energy deposition exceeds a thermodynamic threshold, while photon-induced low-LET interactions are strongly suppressed. Although superheated droplet detectors are established for neutron dosimetry and photon rejection, their use for measuring prompt neutrons from photofission during active photon interrogation has not, to our knowledge, been demonstrated experimentally. Measurements will be acquired with and without uranium under identical beam, geometry, shielding, and temperature conditions. The integrated response will be normalized to irradiation time under fixed beam settings, with beam-current or dose-monitor information used to check the stability of the photon output. A 20°C temperature-controlled bath stabilizes detector response. Polyethylene shielding is placed within the direct solid angle of the converter as seen by the detector, in order to reduce the linac-induced photoneutron component reaching the measurement region. The experiment will test whether uranium produces a reproducible excess above this background and will define requirements for prompt photofission neutron measurements at sub-10 MeV electron energy.

NSS-13-274

Characterization and Comparison of State-of-the-Art Handheld Gamma-Imaging Field Spectrometers (#3056)

Ariel A. Alcaide[1], Juan J. Manfredi[1], Michael Ford[1], Bal Parajuli[2]

[1] Air Force Institute of Technology, Engineering Physics, Dayton, USA; [2] U.S. Air Force School of Aerospace Medicine, Dayton, USA

Abstract

Portable gamma-ray spectrometers with integrated imaging capability represent a significant advancement in field radiation detection by combining radionuclide identification with real-time source localization. These systems have the potential to reduce operator dose through stand-off detection while improving situational awareness in safeguards, emergency response, and radiological assessment missions. This work characterizes and compares two novel handheld gamma-imaging spectrometers: the PHDS GeGI, a mechanically cooled high-purity germanium (HPGe) system, and the H3D H420, a cadmium zinc telluride (CZT)-based detector employing room-temperature semiconductor technology. Baseline performance testing evaluated energy resolution, intrinsic photopeak efficiency, imaging capability, and operational factors including power consumption. Laboratory measurements confirmed that both detectors achieved manufacturer-stated energy resolution at 662 keV, with the GeGI demonstrating superior spectroscopic resolution while the H420 exhibited greater intrinsic photopeak efficiency across much of the tested energy range due to detector geometry and material characteristics. High-gamma-flux testing revealed that the H420 maintained functional spectroscopy and reliable gamma-imaging performance at significantly closer source distances, whereas the GeGI experienced degradation in spectral quality, imaging accuracy, and mission suitability under elevated exposure conditions. The results demonstrate complementary advantages between the two systems: the GeGI provides superior high-resolution isotope identification, while the H420 offers improved operational robustness, imaging stability, and field deployability. These findings support the development of expanded field-performance evaluation frameworks for next-generation gamma-imaging spectrometers and provide guidance for mission-specific detector selection.

Abstract

R3B is a fixed target experiment at the Facility for Antiproton and Ion Research (FAIR) (DE). The setup comprises different sub-detectors that perform kinematically complete measurements of reactions with high-energy radioactive beams. One such sub-detector is the Target Recoil Tracker (TRT), placed in vacuum around a target. The TRT aims to detect light charged particles with an efficiency of ≥ 65 % and provide precise tracking (≤ 10 μm), angular resolution (≲ 2 mrad), and reaction vertex reconstruction, over a large acceptance (≈10° to 90°). It consists of two concentric barrels with radii 5 cm and 6.5 cm, and a total active length of ~ 27 cm. It utilizes silicon Monolithic Active Pixel Sensors (MAPS) thinned down to 50 μm. The ALPIDE sensor, developed by ALICE/CERN, was chosen as its technology is mature and fulfills the R3B detector requirements.

A module consists of 9 chips glued to an aluminum-based Flexible Printed Circuit (FPC) and wire-bonded, with a total material budget of ~ 0.16% X/X_0. The assembly has undergone extensive prototyping through low-, mid-, and high-readiness modules, during which assembly procedures, quality assurance, databases, manuals, and electrical tests were developed in preparation for launching pre-production. The last batch of high-readiness prototypes has been assembled with all final materials and tested. The prototypes show a functional response from all chips, demonstrating the ability to construct fully working production-level modules. Validation tests include a scan of the module with a ^{90}Sr source coupled to an external trigger, and vacuum tests down to 1×10^{-4} mbar. This paper will present the latest developments from the last prototyping stage. UKRI-STFC Laboratories and the University of York aim to deliver 60 production-level modules to FAIR by October 2027.

Development of a Single-Layer Dual-Ended Readout Compton Camera Prototype for Enhanced Spatial Imaging (#1799)

Haoqi Wen, Chenxi Li, Yucun Hou, Kexin Wang, Jianyong Jiang

Beijing Normal University, Key Laboratory of Beam Technology of Ministry of Education, School of Physics and Astronomy, Bejing, China

This work was supported by the NSFC (No. 12475336).

Abstract

The Compton camera has emerged as a pivotal gamma-ray imaging technique, with critical applications in astrophysical observation, nuclear safety monitoring, and environmental radiation detection. In nuclear astrophysics, the detection and localization of gamma rays in the MeV range are indispensable for probing high-energy cosmic phenomena. Despite its importance, the advancement of MeV gamma-ray imaging instrumentation remains constrained by low interaction probabilities and high imaging complexity. This study presents a single-layer Compton camera prototype designed for enhanced spatial imaging, building upon the mission heritage of the BNU-120—a space-borne detector successfully deployed for monitoring gamma-ray bursts (GRBs). To transcend the original system's lack of spatial imaging capability, we propose a high-performance architecture that leverages the established BNU-120 framework while integrating a dual-ended readout to achieve a 4π detection solid angle. The prototype uses a 8×8 Ce:GAGG array coupled to Hamamatsu Multi-Pixel Photon Counters (MPPC, S14161-3050HS-08) at both ends. Each crystal measures 3×3×25 mm^3 and is optically isolated by 0.2-mm-thick $BaSO_4$ reflective layers. System characterization demonstrated an energy resolution of approximately 5% (FWHM) at 511 keV. Depth-of-interaction (DOI) information, extracted via the energy ratio method, yielded a DOI resolution of roughly 2 mm (FWHM) along the crystal axis. Computational validation using GATE simulations of a U-shaped 511 keV planar source showed that the source geometry was clearly distinguishable through a back-projection (BP) algorithm. Subsequent point-source experiments verified the detector's capability to localize discrete sources. Future work will focus on realistic physical imaging experiments and the exploration of more advanced reconstruction algorithms to fully evaluate the module's Compton imaging performance.

Abstract

A 1U-CubeSat payload for the Gamma-Ray Integrated Detectors (GRID) mission has been developed, expanding its scientific scope from transient gamma-ray burst (GRB) monitoring to include space-based neutron lifetime measurements in Low Earth Orbit (LEO). Constrained by a strict form factor (1U, 1.3 kg, 8 W), the payload retains two legacy GAGG scintillators for GRB detection while introducing two novel CLYC-plastic phoswich probes for thermal neutron measurement. To discriminate thermal neutrons within complex orbital backgrounds, the phoswich architecture enables robust pulse shape discrimination (PSD). To mitigate spacecraft-induced secondary neutrons, Gadolinium (Gd) shielding is applied to the sides and backs of both phoswich probes. Furthermore, a differential front-shielding design is employed to extract the thermal neutron flux. An in-orbit Charge Comparison Method (CCM) algorithm is implemented, which optimizes telemetry by processing the PSD signals in real-time, adding only two bytes per event. Ground calibrations demonstrate a neutron-gamma Figure of Merit (FoM) of 1.25, and preliminary cold neutron beam tests validate the differential shielding concept. The payload successfully balances multi-messenger astronomy and fundamental physics goals, verifying its readiness for flight.

Abstract

The ATLASPix3.1 is a full reticle HV-CMOS sensor [1]. It is under study for future lepton colliders [2] and is part of the family of sensors leading to the MightyPix for LHCb and the MuPix for Mu3e. This makes detailed studies of the sensor performance important. We previously reported signal to noise, cluster size and position resolution [3]. Here a detailed study of cross talk and charge collection is presented. Between ATLASPix3.0 and ATLASPix3.1 masks were changed to improve the chip properties at the cost of introducing cross talk. Two types of cross talk were found. Type I yields small signal at fixed positions determined by the hit location. These typically have a signal less than 15% of the original signal. Around 99% of these clusters can be suppressed using a simple minimal signal cut. There is a second type of cross talk hits that yield high signals. An attempt was made to identify these cross talk hits using a gradient-boosted decision tree analysis with variables reflecting cluster shape & signal and signal spread over the pixels. We show that it is not possible to efficiently remove these hits based on cluster properties. This can result in a track candidates with similar χ^2. This can be addressed in an updated design of the sensor and/or by further optimising settings. Using a grazing angle scan the charge collection was studied. In the depletion zone, the charge will be collected quickly. Charge generated in the non-depleted zone will yield a lower and later signal. The depth of the depletion zone was derived as a function of bias voltage. The results show that the depletion depth is proportional to the square root of the bias volrage as would be expected for a planar silicon detector. The experiments have shown that the sensor has very good performance, serving as a promising candidate for future lepton colliders.

Radiation-Tolerant Fast Analogue Pixel Test Structures in TPSCo 65 nm CMOS Technology for the ALICE ITS3 Upgrade (#2439)

Umberto Savino[1,2]

[1] University of Torino, Department of Physics, Torino, Italy; [2] INFN, Section of Torino, Torino, Italy

Abstract

The ALICE ITS3 upgrade represents a major advancement in silicon tracking, exploiting the commercial 65 nm CMOS imaging technology to develop ultra-thin monolithic active pixel sensors (MAPS) for high-energy physics applications. The target detector performance includes an extremely low material budget below 0.09% X0 per layer, with a spatial resolution below 5 μm, and radiation tolerance up to 4×10^{12} 1 MeV n_{eq} cm^{-2}.

Several pixel test structures have been designed and fabricated to investigate both sensor geometries and front-end architectures. In particular, analogue pixel test structures (APTS) featuring a fast operational amplifier (APTS-OA) as output buffer have been developed to study charge collection dynamics and the intrinsic timing performance of the sensor. Measurements performed in charged-

particle beam tests demonstrated a best time resolution of 63 ps, combined with a charge collection efficiency above 99% and a spatial resolution better than 3 μm, while maintaining stable performance up to 1×10^{14} 1 MeV n_{eq} cm^{-2}.

Building on these results, a second engineering run (ER2) introduced three novel chip variants targeting enhanced detector performance and improved radiation robustness. In particular, the optimization of the low-dose n-implant located below the n-well collection electrode aims at reducing the sensor capacitance while enhancing the lateral electric field, thereby improving sensor

depletion and restoring charge collection performance after radiation damage.

This contribution presents the characterization of the new APTS-OA variants and discusses their impact on timing performance, charge collection efficiency, and radiation tolerance through measurements performed on both irradiated and non-irradiated devices.

Laboratory characterization results will be presented providing insight into the effectiveness of the ER2 design optimizations for radiation-tolerant fast MAPS detectors.

Off-detector Readout and Real-time Signal Processing for the ATLAS Liquid ArgonCalorimeter at the High-Luminosity LHC (#2635)

Pablo Collado Soto[2], **Nikiforos Nikiforou**[1], On behalf of the ATLAS Collaboration

[1] CERN, Geneve, Switzerland; [2] Universidad Autonoma de Madrid, Physics Department, Madrid, Spain

Abstract
The ATLAS Liquid Argon (LAr) calorimeter readout electronics are being upgraded for operation at the High-Luminosity Large Hadron Collider (HL-LHC), where up to approximately 200 proton-proton interactions per bunch crossing will significantly increase detector occupancy, data throughput, and trigger rates. While the calorimeter detectors themselves remain unchanged, the full readout electronics chain is being replaced. The upgraded off-detector processing system continuously receives digitized calorimeter signals from approximately 182000 channels at the 40 MHz bunch-crossing rate through high-speed optical links. The processing architecture is implemented in Advanced Telecommunications Computing Architecture (ATCA) systems hosting large FPGAs performing real-time reconstruction of energy and timing while satisfying stringent trigger latency requirements. Prototype hardware and firmware have been developed and validated in integration setups combining front-end electronics, timing distribution, and data acquisition systems. In parallel, advanced reconstruction methods including machine-learning approaches optimized for FPGA implementation are being investigated to improve robustness against pileup and overlapping pulses.

Abstract
Precision physics at future e+e− Higgs factories set stringent requirements on calorimetric performance, with 3%/√E for electromagnetic particles and ∼ 30%/√E for neutral hadrons identified as key benchmarks. A hybrid dual-readout approach, combining a homogeneous crystal electromagnetic section with a fiber-based hadronic section, offers a cost-effective path toward simultaneously achieving both targets. Reaching such performance requires enhancing the longitudinal and transverse granularity of the crystal section beyond what is available in conventional

homogeneous calorimeters and equipping each crystal cell with two independent readout channels to simultaneously collect Cherenkov and scintillation light. These features enable advanced particle-flow dual-readout reconstruction algorithms to exploit the maximum available information from each event. This work will present extensive laboratory characterizations together with beam-test measurements carried out at CERN on single-crystal PWO, BGO, and BSO cells instrumented with optical filters and SiPMs. These studies demonstrate event-by-event separation of Cherenkov and scintillation light, with both scintillation and Cherenkov yields exceeding the thresholds required for optimal electromagnetic and hadronic energy resolution. The results have guided the technological choices for the ongoing construction of full-containment calorimeter prototypes

The LS3 Enhancement of the LHCb Electromagnetic Calorimeter (#2898)

Eduardo Picatoste[1], Sergio Gómez[2], on behalf of the LHCb ECAL Upgrade II RD Group

[1] Universitat de Barcelona, Institute of Cosmos Sciences of the University of Barcelona, Barcelona, Spain; [2] Universitat Politècnica de Catalunya, Barcelona, Spain

Abstract
An upgrade of the LHCb electromagnetic calorimeter (ECAL) is planned for Long Shutdown 3 (LS3) to address significant aging effects in the central region caused by radiation damage and high particle flux. The innermost ECAL modules will be replaced with a new design based on Spaghetti Calorimeter (SpaCal) technology, optimized for radiation tolerance and improved performance under high occupancy conditions. A total of 176 SpaCal modules will be installed. These are based on scintillating plastic fibers embedded in dense absorbers. The innermost 32 modules will use 3D-printed tungsten absorbers to withstand the highest radiation levels, while the remaining 144 modules will employ lead absorbers produced through an innovative casting technique. Both configurations have been prototyped and extensively validated in test beam campaigns at DESY-II and CERN SPS. The measured energy resolution for electron beams is consistent with performance requirements and shows good agreement with detailed Monte Carlo simulations. The scintillating fibers will be read out using radiation-hard hollow light guides coupled to fast photon detectors. In total, 3072 new readout channels will be implemented with dedicated front-end electronics. In parallel with the installation of the new SpaCal modules, the current Shashlik calorimeter modules

will be rearranged to better match the spatial distribution of particle occupancy. Simulation studies demonstrate a significant reduction in per-cell occupancy after the LS3 upgrade, improving detector performance in Run 4 conditions. Benchmark analyses of key physics channels confirm that this enhancement leads to a substantial gain in reconstruction efficiency and measurement precision. Overall, the LS3 ECAL upgrade represents a crucial step toward coping with higher luminosity conditions and anticipates key design features of the future PicoCal system foreseen for implementation during LS4.

Design of the ePIC Hadronic Barrel Calorimeter, Status of the Test stand and Prospects for Physics at the EIC. (#2964)

Eric J. Mannel

Brookhaven National Laboratory, Physics Dept, Upton, USA

This work is supported by the United States Department of Energy.

Abstract
ePIC is the general purpose detector for the Electron-Ion Collider (EIC) that is being built at Brookhaven National Laboratory and will be ready for first physics when the Electron-Ion Collider turns on. ePIC is based on a new 1.7T superconducting solenoid magnet. The detector consists of precision tracking, particle identification and calorimeter (electromagnetic and hadronic) to measure the properties of electron-Ion collisions that will occur at the EIC. In this paper we will present the over all design of the ePIC detector, with a focus on the Barrel Hadronic Calorimeter (BHCal) which is the repurposed sPHENIX Outer Hadronic Calorimeter (HCal). We will also present the current status of the BHCal design, test stand and preliminary results of the new electronics readout system based on the CaloROC chip designed for ePIC

Abstract

In the framework of the ARCADIA collaboration several INFN groups developed a Monolithic Active Pixel Sensor realized in 110 nm CMOS technology capable to operate with fully depleted substrate. Several prototypes embedding different substrate thickness have been produced and tested. In this contribution we detail the design and operation of the first multilayer particle tracking telescope realized with such technology, and successfully tested at the DESY II Test Beam Facility.

The telescope uses 6 tracking planes, each realized with an ARCADIA sensor, and is paired to a 7th layer, the device under test, which was also an ARCADIA sensor, only with a different substrate thickness. The tracking apparatus includes a scintillator based triggering system, a complete synchronization electronics, and a parallel DAQ system for control and data readout.

Together with a brief description of the sensor, the whole telescope system is depicted, detailing the relevant design choices and the expected performances. Maximum rates, resolution and other key metrics are derived from the telescope technical characteristics, and bench-marked against test-beam results. Measured performance are also compared with respect to the gold-standard MIMOSA telescope available at the same test-beam facility, which was used to characterize the same Device Under Test for reference.

A discussion about the strength and weaknesses of the technology, as well as the foreseen improvements and potential applications will close the discussion. Also, potential area of application, both in physics research and in applied fields will be highlighted.

Abstract

This work reports on the experimental characterization, modeling and correction of high intensity effects on the pixel response of the DEPFET Sensor with Signal Compression (DSSC) camera, an active pixel detector targeted at soft X-ray imaging experiments at the European XFEL. Experimental tests with up to 5 MeV/pixel deposited energy have been performed at the European XFEL, showing evidence of a shift of the pedestal value growing with X-ray intensity. Moreover, the signal compression provided by the DEPFET (DEpleted P-type Field Effect Transistor), integrated in each pixel, enhances the impact of this systematic effect on the measurement accuracy. The observed shift is assumed to be proportional to the signal dependent drop of the power supply lines along each ASIC column and can be modeled by two parameters. We devised a procedure to efficiently measure the two model parameters by means of a custom mask that shields a fraction of each ASIC column, irradiated with a flat field. The main results of the characterization of the signal dependent pedestal shift parameters and the application of the resulting correction to X-ray images of different patterned masks (dots, stripes, 2D shapes etc.) acquired at increasing intensities will be presented and discussed.

NSS-13-302

XSTREAM Pathfinder: A Modular R&D Framework for Next-Generation High-Throughput X-ray Detectors at the European XFEL (#1690)

Matteo Porro[1,2], Monica Turcato[1]

[1] European XFEL, Schenefeld, Germany; [2] Ca' Foscari University of Venice, Department of Molecular Sciences and Nanosystems, Venezia, Italy

Abstract

We present the XSTREAM Pathfinder, an exploratory R&D effort at the European XFEL aimed at defining detector technologies for a potential facility upgrade. The activity addresses a broad photon-energy range, from soft X-rays starting at about 250 eV to hard X-rays up to 50 keV, and is structured around three main building blocks: sensor and interconnection technologies, prototype readout ASICs, and a first-stage DAQ system at camera level. The goal is to investigate detector concepts combining pixel sizes of about 100 µm, MHz-rate capability, and flexibility

with respect to possible future XFEL timing structures. Baseline sensor options include silicon diodes and MiniSDDs for soft X-rays, and (thick) silicon diodes for hard X-rays in the 9–12 keV range, with high-Z materials (e.g. CdTe, CZT) considered for extending the operation toward higher photon energies. More advanced options for soft X-rays, including DEPFETs and LGADs, are also under investigation. On the ASIC side, prototype developments will be implemented in scaled CMOS technologies (28 nm or 22 nm), aiming at maximizing the reuse of both analog and digital building blocks across different sensor implementations. While sensor-specific front-end adaptations are required, a common architecture is pursued for key elements such as analog filtering, predictive gain switching, in-pixel digitization, and high-speed data serialization. A central challenge is the development of a high-throughput readout enabling continuous operation at up to 1 MHz, opening the path toward CW or high-duty-cycle modes, while maintaining backward compatibility with burst-mode operation. The Pathfinder will progressively validate the readout chain from sensor to digital output, including early studies of DAQ-level real-time data reduction.

Abstract
The Data Acquisition (DAQ) system of the DEPFET Sensor with Signal Compression (DSSC) megapixel (Mpx) camera at the European X-ray Free-Electron Laser (EuXFEL) is being revisited to support higher-performance detectors. The current digital front-end consists of two Field-Prgrammable Gate Array (FPGA)-based stages: the Input Output Board (IOB), responsible for initial data acquisition from Application Specific Integrated Circuits

(ASICs), and the Patch Panel Transceiver (PPT), which manages data reordering and remote control. In the present 1-Mpx configuration with 9-bit pixel resolution, each IOB serves 16 ASICs (0.29 Gbps), four IOBs form a quadrant (18.88 Gbps), and four PPTs handle the full camera (75.49 Gbps). Since the AISCs and IOBs operate inside a vacuum enclosure at about −20 °C, any upgrade must comply with strict constraints on size, power delivery, and thermal management. In this context, EuXFEL is exploring both near- and long-term upgrade paths driven by the evolution of DSSC toward a 4-Mpx detector with 10-bit pixel resolution and higher throughput. The current system stores about 8,000 frames per second out of the 27,000 pulses per second produced by EuXFEL; near-term targets are 10,000 fps and 27,000 fps, while the long-term goal is continuous operation up to 1 Mfps. These modes would increase the required data transfer rate by factors ranging from about 5.55 to 15 in the near-term, and up to 555 in the long-term scenario, highlighting the main limitation of the current IOB. The IOB must be redesigned with a more powerful FPGA to meet near-term targets while enabling advanced data processing for long-term scenarios (e.g., lossless compression). The current capacitor bank—a simple power approach for DEPFETs—is therefore reconsidered; its removal frees up to about 50% of the IOB area, allowing the integration of additional memory and paving the way toward significantly higher data rates.

NSS-13-306

Towards a 64-Channel Monolithic SDD X-Ray Spectrometer for High-Throughput Synchrotron Applications (#2776)

Beatrice Pedretti[1,2], Pietro Barcella[1,2], Andrea Abba[3], Giacomo Borghi[1,2], Marco Carminati[1,2], Carlo E. Fiorini[1,2]

[1] Politecnico di Milano, DEIB, Milano, Italy; [2] INFN, Milano, Milano, Italy; [3] Nuclear Instruments srl, Lambrugo, Italy

Abstract

The increasing brilliance of fourth-generation synchrotron sources drives a growing demand for energy-dispersive X-ray fluorescence (XRF) spectrometers capable of handling extreme photon fluxes.

We present the design and characterization of the ARDESIA-64 instrument, a complete X-ray fluorescence (XRF) spectrometer for high-throughput synchrotron applications.

The instrument integrates a highly scaled 64-channel monolithic Silicon Drift Detector (SDD) array, featuring a pixel pitch of 2.5 mm, within a compact, vacuum-compatible mechanical housing tailored for beamline integration.

At the conference, we will present the instrument design and comprehensive spectroscopic characterization results.

The collimated 450 µm-thick sensor variant demonstrates an excellent average energy resolution of 125.9 eV FWHM at 5.9 keV. Preliminary high-rate tests confirm exceptional throughput capabilities, sustaining Input Count Rates (ICR) exceeding 800 kcps per channel while preserving an energy resolution of ~150 eV. The readout is performed by a 64-channel Digital Pulse Processor (DPP) based on the CAEN DT5560SE digitizer with firmware specifically adapted for high-throughput X-ray spectroscopy in synchrotrons.

Abstract

Conducting isotopic level material control and accountancy of radioactive materials in fluids is challenging for multiple reasons: optical and electronic methods only provide elemental information, gamma-based methods face difficulties quantifying total concentrations, and destructive mass spectroscopy is costly and time consuming. Alpha-based techniques are typically not feasible due to the particles short (10-20 μm) range in dense matter and often require radiochemical separations in conjunction with electroplating. In this presentation we will present a novel sensor design that utilizes microfluidic structures which constrain the sample to a thin volume, limiting the energy loss of alpha particles, enabling spectroscopic measurements. If the alpha-particle energy is properly conserved it will allow for identification of the isotopes present, while the known sample volume will provide a means of calculating the isotope mass and subsequent concentration.

Abstract

The rhizosphere is the zone surrounding plant roots where there is mutual influence exerted between soil microbes and the roots. In this zone biological and chemical activity is driven by compounds exuded by or present in the root and consumed by specialized types of fungi and bacteria that inhabit or surround the roots. Understanding the dynamics occurring in the rhizosphere regarding plant-microbe, plant-plant and microbe-microbe interaction is the focus of much plant ecophysiology research. Plant biologists often use radioisotopes of carbon, iron, phosphorous and calcium to study this plant-microbe interaction but their radioisotope imaging methods are static and destructive. The Beta Rhizotron is a beta (b)particle imaging detector designed for dynamic, non-invasive, *in-vivo/in-situ* imaging of plant roots being studied using b-particle emitting radioisotope tracers. Potential tracers include ^{14}C, ^{32}P, ^{45}Ca and ^{64}Cu via detection of their emitted b-particles from roots grown in a special container called a rhizotron/rhizobox. The detector is a gas based charged particle detector known as a micro-pattern gaseous detector (MPGD). Large area MPGDs are used in particle physics research. The use of a MPGD coupled to a rhizobox for low energy b-particle detection requires an MPGD able to operate in a varying temperature and humidity environment of standard growth chambers to obtain dynamic images of the bio-distribution of b-particle emitting radioisotopes. A key optimization of MPGD construction we are reporting here is the choice of window material.To estimate the expected 2-D intensity histograms simulations were performed using GEANT4 for ^{64}Cu with the b+ endpoint energy of ~0.65 MeV.Simulated was an 8 μm Kapton window, a 6 μm aluminized Mylar MPGD cathode/window, a 3 mm thick MPGD drift gas volume and a 1 x 1 x 70 mm^3 water column with a uniform spatial distribution of the β-particle emitter to approximate a root. Results indicated adequate imaging results.

True Random Number Generation for Post-Quantum Applications

(#1622)

Edward Cazalas, Cara Blick

University of Utah, Nuclear Engineering Program, Salt Lake City, USA

None

Abstract

This project advances a self-contained, portable True Random Number Generator (TRNG) grounded in the quantum-physical randomness of radioactive decay, integrated with an AI-driven monitoring and adaptive control system, for post-quantum cryptography (PQC) in mission-critical environments where remote connectivity is unavailable or constitutes an unacceptable security risk. Conventional cryptographic methods are projected to be vulnerable to quantum computing attacks by 2030, and NIST has mandated migration to PQC standards (FIPS 203–205) by 2030–2035. A fundamental requirement of PQC is a hardware TRNG capable of producing certified entropy without software-based pseudo-randomness. Existing solutions, e.g., cloud-connected beacons, large optical facilities, are incompatible with the remote, radiation-exposed, and network-denied settings of nuclear power plants, satellites, submarines, and forward military installations. Silicon SoC (system on a chip)-based TRNGs further fail in these environments, as ionizing radiation effects (total ionizing dose, single event upsets, direct damage) can bias, degrade, or manipulate their entropy output. Radioactive decay is a quantum-physical process that is intrinsically random, radiation-environment-tolerant, and scalable to NRC-exempt activity levels, making it ideally suited to this application.

Optimization of working point for TES microcalorimetric gamma spectroscopy (#2121)

Nolan I. Kowitt, Areg Danagoulian

Massachusetts Institute of Technology, Nuclear Science and Engineering, Cambridge, USA

This work was partially supported by the NSSC4 Consortium under grant number DE-NA0004277.

Abstract

Cryogenic microcalorimeters are low-noise thermal detectors that have demonstrated gamma-ray resolution better than 100 eV at 100 keV, resolving lines unresolvable by conventional spectrometers. Achieving this resolution with an array of transition-edge sensors (TESs), however, requires that all TESs, each with a slightly different transition temperature, be simultaneously biased near their individual operating points. Because the TESs on a given readout line share a common bias, ensemble performance is determined by global parameters: the mixing-chamber temperature, the TES bias current, and the readout electronics configuration. A parametric study was performed to identify the operating point that maximizes the number of usefully contributing pixels and the combined energy resolution. Results of this study will be discussed, along with the methodology for combining and analyzing spectra across the array.

Radiation Damage to Quantum Dots (#2264)

Jesse Snow, Edward Cazalas

university of Utah, Nuclear Engineering Program, Salt Lake City, USA

We would like to thank faculty and staff at the University of Utah NanoFab and Materials Characterization Lab for their assistance in measurement systems use and training. This material is based upon work supported by the Consortium for Nuclear Forensics (CNF) under the U.S. Department of Energy (DOE) National Nuclear Security Administration (NNSA) award number DE-NA0004142.

Abstract

QD nanostructures have emerged as highly versatile materials for sensing ionizing radiation. However, comparatively little is known about how QDs respond to non-ionizing radiation such as fast and thermal neutrons, where neutron capture, rather than ionization, is the dominant interaction mechanism. This study examines the viability of graphene QDs as neutron dosimeters or neutron–gamma discriminators. Additionally, research into QDs can aid in nuclear non-proliferation and dosimetry. The goal of this research is to investigate the effects of neutron irradiation on the optical properties of graphene QDs for non-proliferation applications. The results of this work provide insight into the mechanisms through which neutrons alter QD electronic structure and optical response. This study will contribute to the broader effort to develop hybrid or stand-alone QD-based radiation sensors and markers capable of operating across diverse radiation environments and even being incorporated into fuel.

This work was partially supported by a travel grant from the Dentsu Scholarship Foundation. The authors gratefully acknowledge their financial support for participation in this international conference.

Abstract

Transition-edge Edge Sensor (TES) microcalorimeters (TES) are attractive promising detectors for gamma-ray spectroscopy because of their excellent energy resolution[1]. However, TES detectors microcalorimeters generally have small sensitive effective areas, and large-scale arrays are required to achieve high detection efficiency. Since TESs operate at cryogenic temperatures, increasing the number of TESs increases Joule heating and readout complexity.

To address this issue, a Position-Sensitive TES (PoST) structure microcalorimeters haves been proposed to realize a large effective detection area with a small number of TESs. The Our gamma-ray PoST consists of a long lead absorber with TESs attached to both ends, and the incident position of gamma rays is estimated from differences in pulse shapes.

In this study, we evaluated the energy resolution and position resolution of the PoST detector by simulations considering thermal intrinsic noise and gamma-ray multiple scatteringinteractions. The simulations were performed using a finite element model coupling thermal conduction and TES electrical circuits. Sub-millimeter position resolution was achieved for 1333 keV1.33 MeV gamma rays.

This instrument development has been funded by CNES and supported by EXAIL & Laboratory Hubert Curien, through their joint laboratory LABH6.

Abstract

Optical-fiber dosimetry, based on Radiation-Induced Attenuation (RIA) or Radiation-Induced Luminescence (RIL), has progressed from particle-accelerator research to space applications. The first space-borne implementation, the LUMINA experiment, flew on the International Space Station during the ALPHA mission. LUMINA used several kilometres of specially selected silica fiber to provide dose-rate-independent, temperature-independent, and particle-type-independent measurements, successfully monitoring the ISS radiation environment, including each passage through the South Atlantic Anomaly.

To meet the more demanding radiation levels, mass, volume, and power constraints of CubeSat missions, we have miniaturized the LUMINA architecture into GlowRIA. In this new design, the fiber length was reduced to a few hundred metres and can be adjusted according to the expected mission dose. The optoelectronics, including the laser and photodiodes, were selected for lower power consumption and a more compact form factor. In addition, the read-out electronics were replaced by a radiation-tolerant microcontroller, eliminating the Raspberry-Pi board used on LUMINA and ensuring resilience to both cumulative dose effects and single-event effects.
GlowRIA has been subjected to a comprehensive qualification campaign reproducing harsh orbital conditions such as vacuum, large temperature excursions, electromagnetic interference, and total ionizing dose. The tests confirm that the dosimeter retains its performance while meeting CubeSat power and mass budgets.
We are also conducting Total Ionizing Dose calibration of the instrument using a Co-60 source, while Single Event Effects testing is planned at a later stage. The results of the environmental, radiation, and performance qualification campaigns will be presented in the full article.

Scintillation imaging with Coded Aperture masks (#2853)

Valentina Cicero[1], Nicolò Tosi[1], Alessandro Montanari[1], Valerio Pia[1], Filippo Mei[3,1], Luigi Martina[2], Giovanni De Matteis[2]

[1] Istituto Nazionale di Fisica Nucleare, Bologna, Bologna, Italy; [2] Università del Salento, Mathematics and Physics, Lecce, Italy; [3] Università di Bologna, Physics and Astronomy, Bologna, Italy

This work is part of the project “Imaging calorimetry in scintillating media for high energy physics and tomography” (PRIN 2022KJZSYB), funded by the European Union Next Generation EU, Mission 4, Component 1, CUP I53D23001230006.

Abstract
Large volumes of liquid argon or xenon serve as highly effective media for detecting neutrino interactions and searching for dark matter. Conventional noble-liquid detectors typically use scintillation light for timing or calorimetric measurements only, while relying on charge drift in a time projection chamber for spatial reconstruction.
Direct optical reconstruction of events by imaging scintillation light could provide an alternative to the slow charge collection, also eliminating the necessity for an electric drift field. The increased rate capability enables new applications, including detectors at high-intensity neutrino beams and medical imaging (whole-body PET).

Thanks to finely segmented Silicon PhotoMultiplier arrays and appropriate optical systems, it is feasible to create cameras capable of ``photographing" the primary scintillation light. A significant challenge is presented by the fact that both argon and xenon emit scintillation light in the vacuum-ultraviolet spectrum. To overcome this, coded aperture masks are employed instead of conventional lenses, enabling the construction of thin cameras with wide and deep fields of view. A reconstruction algorithm based on Maximum Likelihood Expectation Maximization has been developed to generate a 3D map of energy deposition. The most recent results from simulations and reconstructions of particles tracks in a liquid argon detector equipped with these cameras will be discussed.

Application of a Compact Electrically Cooled HPGe Detector to Quality Control in Radiopharmaceutical Isotope Production (#2856)

Gabriela Ilie

Mirion Technologies, Radiometric Physics, Meriden, USA

Abstract

Since their invention in the 1970s, high purity germanium (HPGe) detectors have been the gold standard for the detection and spectroscopy of gamma rays. Developments in the fabrication, packaging, and operation of HPGe detectors, as well as in readout electronics and signal processing, have led to their application in fields as diverse as fundamental nuclear and particle physics, nuclear security and safety, and nuclear medicine. Based on decades of experience in electrical cooling technology, in recent years Mirion Technologies has developed rugged germanium detectors that can be used in difficult conditions traditionally considered too challenging for HPGe detectors. An example of such a detector is our newest product: the MicroGe detector. Due to it is small form factor and rapid deployment capability, the MicroGe detector can be used in medical radioisotope production facilities where high resolution is critical to identify impurities in samples. The MicroGe detector is capable of going from storage to measurement in less than 30 minutes which is a revolutionary achievement for HPGes. This paper presents results of the evaluation of a novel ultra-compact electrically cooled germanium detector as a quality-control instrument for quantification of for radionuclide impurity of samples.

Graphene-Based Front-End Amplifier for Nuclear Instrumentation (#2349)

Marcos Turqueti[1], Alec Lindman[2], Om Aggarwal[1], Alan Poon[2]

[1] Lawrence Berkeley National Laboratory, Engineering Division, Berkeley, USA; [2] Lawrence Berkeley National Laboratory, Nuclear Science Division, Berkeley, USA

Abstract

Front-end electronics for nuclear instrumentation require ultra-low noise, high bandwidth, radiation tolerance, and low power consumption to accurately process weak signals generated by radiation detectors. Conventional silicon-based amplifiers face increasing limitations in applications demanding extreme sensitivity, cryogenic operation, and compact integration. This work investigates the use of graphene-based electronic devices as a novel platform for next-generation front-end amplifiers for nuclear science applications. Owing to its exceptional carrier mobility, high thermal conductivity, mechanical flexibility, and potential for low-noise operation, graphene presents a promising alternative material for advanced detector readout electronics.

We present the conceptual design and preliminary evaluation of a graphene-based front-end amplifier architecture intended for integration with nuclear radiation detectors including silicon photomultipliers (SiPMs), cadmium zinc telluride (CZT) detectors, and other low-signal sensing systems. The proposed approach focuses on achieving improved signal amplification while minimizing electronic noise and power dissipation. Device-level considerations including transconductance behavior, impedance matching, frequency response, and low-temperature performance are analyzed to assess suitability for nuclear instrumentation environments.

Theoretical analyses indicate that graphene-enabled amplifier structures can provide enhanced sensitivity and bandwidth compared to conventional semiconductor implementations, particularly in low-temperature and low-signal regimes relevant to modern nuclear physics experiments and radiation detection systems. The results demonstrate the potential of graphene-based front-end electronics as an enabling technology for next-generation nuclear instrumentation, with applications spanning particle physics, medical imaging, homeland security, and advanced scientific sensing platforms.

ToRA : a 64-channel ASIC for the readout of gaseous detectors in a CMOS 65 nm technology (#1949)

Giovanni Mazza[1], Maxim Alexeev[1,2], Oleg Denisov[1], Lorenzo Marcellino[2], Chiara Alice[2], Marco Mignone[1], Richard J. Wheadon[1]

[1] INFN - Istituto Nazionale di Fisica Nucleare, Sezione di Torino, Torino, Italy; [2] Università di Torino, Dipartimento di Fisica, Torino, Italy

Abstract

ToRA is a 64 channel ASIC for the readout of gaseous detectors used in high energy physics experiments. Its driving application is the readout of the MicroMega detectors for the AMBER experiment upgrade. However, it is designed to be highly flexible in order to be used also for other types of gaseous detectors, e.g. straw detectors. Each ToRA channel provides programmable signal amplification and shaping. The ASIC provides the time measurement of the time of arrival, the time over threshold and the peak position of the shaper signal. Moreover, the peak value is hold and converted with a single ramp ADC.

A fully digital interface, based on differential serial links and including a data and a control interface, has been implemented. The events are packed into 32-bit words and transmitted over two 200 Mb/s links.

This work is supported by Horizon Europe under Grant 101130550 (i-RASE).

Abstract

This work presents an 8-channel ASIC designed in 180 nm CMOS technology for γ-ray spectroscopy as part of the EU-funded project i-RASE. i-RASE aims at developing a novel generation of radiation detectors capable of performing real-time processing by adopting artificial neural networks (ANN) to reconstruct energy, position, and timing of incoming photons. The ASIC is specifically tailored for room temperature detectors, featuring large detector capacitance (up to 50 pF), like CdZnTe. It includes dual-polarity charge sensitive amplifiers (CSA) with pulsed-reset and leakage current compensation (LCC), sample-and-hold circuitry controlled by a digital logic shared among the channels, and both single-ended and differential output architectures. Two readout modes are supported: a continuous mode, compatible with conventional analog and digital readout and shaping chains, and a high-speed sampling mode, in which a switched capacitor array (SCA) continuously samples the analog output of the CSA at frequencies up to 100 MHz. The samples are stored in 256 capacitors and subsequently buffered to an external differential ADC, triggered by the ASIC event thresholds, and controlled by the FPGA running the ANN. The preliminary results of the ASIC characterization (rise time of 100 ns, linearity of 0.5%), performed by injecting test signals, are presented and match simulations.

Abstract

This work presents the design and experimental characterization of a prototype channel developed in a 65 nm CMOS process for the readout of the large-area lithium-drifted silicon detectors of the General Antiparticle Spectrometer tracker. To simultaneously achieve high-resolution X-ray spectroscopy below 100 keV and a wide dynamic range up to 100 MeV, the charge-sensitive amplifier employs a dynamic-threshold MOS feedback capacitor exploiting dynamic signal compression. An enhanced Krummenacher network provides continuous feedback discharge, compensating detector leakage currents up to 200 nA. Experimental results demonstrate an energy resolution of 3.2 keV full width at half maximum (379 e^- rms equivalent noise charge) and an integral

nonlinearity below 1.5%. A compensation technique to mitigate temperature-induced variations in the charge-sensitive amplifier response is also presented.

Abstract

We present the first measurements for the third revision of the High Pitch digitizer System-on-Chip (HPSoC), a 9 channel Readout Integrated Circuit (ROIC) prototype. The HPSoC concept is that of a high channel density and scalable waveform digitization ROIC with an embedded interface to advanced high-speed sensor arrays such as e.g. AC-LGADs. The chip was fabricated in 65nm technology and targets picosecond-level timing resolution via high speed waveform sampling (in excess of 10 Gsps), autonomous chip triggering and feature extraction. In this paper, we present the results of testing of the chip's timing generation and digitization.

Abstract

The LEGEND (Large Enriched Germanium Exper iment for Neutrinoless double beta Decay) experiment aims to detect neutrinoless double beta decay (0νββ) in 76Ge using large scale cryogenic germanium detectors. A 0.35µm LUIGI ASIC was designed as a detector readout, ensuring low noise and high radiopurity conditions. Such front-end ASIC, when assembled to the Ge detector, must operate at cryogenic temperatures, typically 87 K using liquid argon (LAr). At cryogenic temperatures, semiconductor characteristics shift significantly, while standard transistor models, typically validated only to −55◦C (218.15 K), become inaccurate. therefore, this work presents a workflow for cryogenic MOSFET modeling based on BSIM4, using experimen tal data measured at 77 K. The model is extracted from mea surements at both room and cryogenic temperatures, validated with corresponding Cadence models at room temperature, and is then used to assess the impact of cryogenic effects on analog circuit performance. Further experimental characterization on a new set of transistors will be made is required to refine and improve the accuracy of the model.

Abstract

X-ray fluorescence analysis is a fast, non-destructive technique for material characterization and recycling, where silicon drift detector-based systems provide high energy resolution. Portable applications require a high integration density, while conventional state of the art solutions depend on external highvoltage electronics occupying more than 250 mm^2. To address this challenge, this work presents an application-specific integrated circuit fabricated in 180 nm silicon-on-insulator technology that generates all negative high voltages required for silicon drift detector operation in the range from -20 V to -130 V. Each voltage supply is implemented using a CMOS DC/DC converter based on a Pelliconi charge pump. The employed topology utilizes low-voltage transistors and a simple two-phase clock scheme driven by a ring oscillator at 10 MHz, enabling high efficiency while reducing chip area. The stability, noise, and spectral performance of a silicon drift detector operated with the proposed charge-pump-based supply is compared to those obtained with a conventional power supply. The results show that operation of a silicon drift detector module using an external ASIC-based charge pump is possible with high energy resolution for peaking times exceeding 1 µs, provided that the generated voltages are sufficiently smoothed using external capacitors. These results facilitate the development of more compact and cost-effective silicon drift detector power supply solutions.

Abstract

The Analog Spectral Imager for X-rays (ASIX) is a technology demonstrator for a Hybrid Pixel Detector (HPD) aimed at delivering high-resolution measurements in both spatial and energy domains, thus enabling advanced X-ray spectral imaging. ASIX features 50~μm pixels arranged into a hexagonal array. An in-pixel ultra-low noise front-end (<30 ENC at Cd=100 fF), together with a self-triggering logic, and a highly segmented readout, enables precise identification of the charge clusters on a photon-by-photon basis.

The readout architecture is based on regions. Each region comprises a 16 X 8 pixel matrix and dedicated readout electronics including a compact 10-bit SAR ADC, a data-out FIFO and the readout-controller sequencing logic. The full demonstrator chip will be composed of a 6 X 12 array of regions, corresponding to a 96 X 96 pixel matrix, together with a digital output logic responsible for collecting, formatting and serializing data.

We developed a 2 X 2 mm^2 prototype readout chip in a commercial 65 nm CMOS process featuring a fully functional region.

Given its 4-side abuttable layout and its almost exclusively digital interfaces, this can be regarded as the main building block for readout matrices in larger-scale ASICs such as the future full-scale demonstrator.

Abstract

To ensure the safe decommissioning of the reactor buildings at the Fukushima Daiichi Nuclear Power Station, it is essential to reduce the external exposure of workers. In order to achieve this objective, it is necessary to accurately estimate the distribution of [if gte msEquation 12]><m:oMath><m:sPre><m:sPrePr><span style='font-family:"Cambria Math",serif;mso-ascii-font-family:"Cambria Math"; mso-hansi-font-family:"Cambria Math";color:black;mso-themecolor:text1; mso-fareast-language:JA;font-style:italic;mso-bidi-font-style:normal'><m:ctrlPr></m:ctrlPr></m:sPrePr><m:sub></m:sub><m:sup><span lang=EN-US style='font-size:10.0pt; font-family:"Cambria Math",serif;mso-fareast-font-family:游明朝;mso-fareast-theme-font: minor-fareast;mso-bidi-font-family:"Times New Roman";color:black;mso-themecolor: text1;mso-ansi-language:EN-US;mso-fareast-language:JA;mso-bidi-language: AR-SA'><m:r>137</m:r></m:sup><m:e><span lang=EN-US style='font-size:10.0pt;font-family:"Cambria Math",serif;mso-fareast-font-family: 游明朝;mso-fareast-theme-font:minor-fareast;mso-bidi-font-family:"Times New Roman"; color:black;mso-themecolor:text1;mso-ansi-language:EN-US;mso-fareast-language: JA;mso-bidi-language:AR-SA'><m:r><m:rPr><m:scr m:val="roman"/><m:sty m:val="p"/></m:rPr>Cs</m:r></m:e></m:sPre></m:oMath><![endif] contamination density — the primary source of external exposure — and to evaluate dose rates in each working space within R/Bs with high precision. 3D Air Dose Rate Evaluation System -Indoor (3D-AI) estimates distributions of contamination density and dose rate in the working space using dose-rate data and point clouds via LASSO regression. In this work, we introduce an L2-normalization method that balances each source's contribution to measurement points to improve sensitivity to remote contaminations. To test the ability of this method, we analyzed data measured near the startup transformer of the Fukushima Daiichi Nuclear Power Station Unit 3 and compared them with maps estimated by the Compton camera. Results show that both conventional and new systems estimated contamination distributions and dose rates with high accuracy near the measurement points. In contrast, in areas distant from measurement points, the

new method better matches the Compton images and improves surface dose-rate estimates, reducing the ~1/50 underestimation to within a few factors.

Template-Based Decomposition of Gamma Spectra for NORM Quantification (#2804)

Massimo Morichi, Bruno Angelucci, **Fabio Davolio**, Cristiana Del Bene, Erica Fanchini, Paola Garosi, Carlo Uguccioni

CAEN S.p.A., Viareggio, Italy

Abstract
This paper describes a template-based gamma spectral decomposition algorithm developed for quantitative analysis of Naturally Occurring Radioactive Material (NORM). The method uses a Monte Carlo-simulated template to decompose measured spectra into contributions from the 40K, and the 238U and 232Th decay chains, and to estimate the corresponding absorbed dose rates. The algorithm is integrated into the CAEN Gamon-Drone platform and supports both $CeBr_3$ and NaI(Tl) scintillation detectors. The proposed approach addresses two operational scenarios. In airborne surveys, dynamic integration and spectral reweighting are applied to continuously acquired spectra to reduce statistical fluctuations. This processing improves detection sensitivity and allows for high-resolution radiological mapping. In ground-based measurements, the same analytical framework provides rapid in situ characterization of soils, rocks, and construction materials through direct estimation of radionuclide concentrations. Validation tests showed strong consistency between reconstructed activities and reference values for multiple detector configurations and environmental conditions. The results demonstrate that Monte Carlo template decomposition can provide accurate and robust NORM quantification using compact scintillation-based gamma spectroscopy systems.

Enhancing Low-Energy MVT Bi-exponential Convergence via Adaptive Initial Value Estimation (#2818)

Bowen Xu, **Bowen Xu**, Hao Lan, Hao Lan, Guanning Su, Guanning Su, Qingguo Xie, Qingguo Xie

University of Science and Technology of China, Department of Electronic Engineering and Information Science, Hefei, China

Abstract

Multi-Voltage Threshold (MVT) technology, serving as an advanced method for scintillation pulse digitization, achieves pulse waveform reconstruction and energy calculation in PET systems through a bi-exponential model. However, with the gradual application of crystal miniaturization and 1:1:1 readout technologies, the fitting of low-energy pulses faces severe convergence challenges. This leads to a large number of pulses being discarded, which severely restricts system sensitivity. To address this issue, this paper proposes an effective initial value estimation method. Experiments were conducted using four-threshold MVT sampling and bi-exponential fitting, utilizing the Root Mean Square Error (RMSE) of the fitted waveforms, the proportion of severe deviations, the absolute mean of the pulse area relative error, and the standard deviation as evaluation metrics. Results on low-energy band pulses (40-150 keV) indicate that after utilizing the proposed initial value estimation method, the waveform RMSE was effectively restricted, and the three relative area error metrics were improved by 61.5%, 105.8, and 341.0, respectively, thereby significantly reducing fitting convergence failures.

Abstract

Muon scattering imaging (MSI) is sensitive to high-Z materials; however, the inherently low cosmic muon flux usually requires long acquisition times to achieve acceptable image quality. To address this limitation, we propose a statistically enhanced dual-modality muon imaging framework based on trigger redesign in a muon scattering tomography system consisting of 8 detector layers. By relaxing the conventional strict coincidence requirement and redesigning the event selection logic, previously discarded non-penetrating muon events can be effectively incorporated into muon absorption imaging (MAI), while penetrating events are retained for MSI reconstruction. This event reutilization significantly increases the effective statistics without additional hardware, thereby improving imaging efficiency and reducing the required measurement time.

To further exploit the complementary information from MAI and MSI, multiple image fusion methods were investigated, including linear weighted fusion, Fourier decomposition filtering fusion, and Principal Component Analysis-based fusion. Experimental results show that the maximum a posteriori (MAP)-based fusion method achieves the best reconstruction performance. Imaging experiments were conducted using an eight-layer 50 cm × 50 cm plastic scintillator detector system. The target consisted of fifteen 5 cm × 5 cm × 5 cm lead blocks arranged in a U-shaped structure. A total of 4.3 × 10^4 muon events were collected. Compared with conventional MSI reconstruction, the proposed framework produces clearer structural boundaries, higher contrast, and significantly suppressed background noise. Quantitative evaluation using the structural similarity index (SSIM) shows an improvement from 0.212 to 0.389, corresponding to an increase of approximately 83%.

The proposed trigger optimization and image fusion strategy enable faster, higher-quality, and more practical muon scattering imaging for security and high-Z material identification.

Abstract

This work investigates Inverse Compton Scattering (ICS) sources and their potential for synchrotron-based medical applications, particularly Microbeam Radiation Therapy (MRT). As compact alternatives to large synchrotron facilities, ICS sources are rapidly approaching the flux and energy requirements necessary for MRT, but require detailed characterisation before clinical implementation can be considered. Geant4 Monte Carlo simulations inspired by the ThomX ICS source were performed to evaluate the influence of key source parameters on the emitted x-ray spectrum. Parameters studied included electron beam energy, energy spread, emittance, and laser wavelength. The simulations show that variations in these parameters produce measurable shifts in spectral peak energy, directly relevant to MRT beam optimisation, as well as asymmetric spectral broadening across the spectrum. These results are the first ICS simulations of these parameters at MRT relevant energies and aid the evaluation of ICS sources as compact alternatives to synchrotron radiation sources.

Abstract

Radiomics analysis in nuclear medicine is commonly performed on predefined features extracted from individual regions, which limits its ability to describe global imaging patterns across the whole body. In this work, we propose a latent-space digital twin framework to characterize multi-organ radiomics behavior in theranostic SPECT/CT imaging. Post-therapy SPECT/CT data from 57 patients treated with ^{177}Lu-based radiopharmaceuticals were analyzed. Multi-organ and lesion segmentations were obtained, and 107 standardized radiomics features were extracted for each region. These features were aggregated into patient-level representations and projected into a low-dimensional latent space using principal component analysis. Unsupervised clustering and distance-based analysis were then applied to identify underlying radiomics phenotypes and quantify inter-patient variability. The learned latent space revealed structured organization of radiomics patterns, with the first two principal components capturing more than half of the total variance (PC1: 34%, PC2: 19%). Distinct patient groups emerged with clear separation, characterized by lower intra-group distances (≈6) and substantially higher inter-group distances (≈12). Analysis of latent components indicated that structural regions predominantly contributed to the first component, while soft-tissue and vascular regions influenced the second component. In addition, the latent representation enabled identification of outlier patients, reflecting substantial heterogeneity in multi-organ radiomics profiles. These findings demonstrate that latent-space modeling provides a compact and interpretable representation of complex radiomics data. The proposed digital twin framework enables system-level phenotyping and may support improved patient stratification in theranostic SPECT/CT imaging.

Asymmetry in time difference histograms for scintillators with different decay constants in coincidence (#2202)

Akram Hamato[1,2], Nicolaus Kratochwil[2], Ryosuke Ota[2,4], Jarek Glodo[3], Taiga Yamaya[1], Simon R. Cherry[2], Sun Il Kwon[2]

[1] National Institutes for Quantum Science and Technology (QST), Advanced Nuclear Medicine Sciences, Chiba, Japan; [2] University of California Davis, Biomedical Engineering, Davis, USA; [3] Radiation Monitoring Devices Inc., Watertown, USA; [4] Hamamatsu Photonics K.K, Central Research Laboratory, Hamamatsu, Japan

This work was supported by the National Institutes of Health under grant R01 EB030538.

Abstract

Coincidence timing resolution is a critical performance parameter in time-of-flight PET and other timing sensitive applications. The timing performance of scintillation detectors is governed by intrinsic scintillator properties such as light yield, rise time, and decay constant. When detectors with different scintillation characteristics are in coincidence, these differences can distort the coincidence timing spectrum, leading to deviations from an ideal symmetric Gaussian distribution. Differences in scintillator decay constants can introduce measurable asymmetry in coincidence timing histograms. In this work, the influence of scintillator decay constant on coincidence timing histogram was investigated using several scintillators with different decay constants. The scintillators (Lu_2O_3:Yb, EPS-100 plastic scintillator, $LaBr_3$:Ce, LYSO:Ce, GAGG, NaI:Tl, and BGO) with dimensions of 3×3×5 mm^3 mounted on identical silicon photomultipliers were placed in coincidence with a reference LYSO detector. Time difference histograms were acquired for each detector pair and quantitatively analyzed using the mean, median, and skewness of the measured distributions. The results showed nearly symmetric timing histograms for EPS-100, $LaBr_3$, and LYSO scintillators, whereas other scintillators exhibited increasing asymmetry. The longest tail was observed for BGO on one side of the histogram. Time difference histograms were also analytically calculated based on the arrival time distribution of the 10th detected photon. The analytical results reproduced the main trends observed experimentally. These findings demonstrate that scintillator decay constants significantly influence the shape and asymmetry of coincidence timing histograms for non-identical detector pairs with substantially different decay constants, providing insight relevant to the design and optimization of mixed scintillator timing systems.

Ultrafast and Efficient 2D Perovskite Scintillators for Sub-50 ps TOF-PET and High-Resolution X-ray Imaging (#2541)

Jiaqi Liu

Wuhan University of Technology, School of Materials Science and Engineering, Wuhan, China

Abstract

Ultrafast radiation detection has been persistently limited by the formidable challenge of achieving scintillators that combine sub-nanosecond response times with high scintillation efficiency. Here, we identify atomic-level exciton confinement, achieved through the synergistic regulation of A-site organic cations in 2D perovskites, as a critical factor for breaking this performance bottleneck. The resulting (1,4-CMA)$PbBr_4$ crystals exhibit a rare combination of a 0.62 ns radioluminescence decay time and a high light yield of 19,730 photons/MeV, surpassing leading commercial benchmarks such as BaF_2 and LYSO:Ce. Detectors based on this material achieved a record-breaking coincidence timing resolution (CTR) of 43.3 ps for reconstruction-free Time-of-Flight Positron Emission Tomography (TOF-PET) and a high spatial resolution of 32.3 lp mm^{-1} for X-ray imaging. These results establish rational lattice distortion engineering as a key principle for the development of high-performance, scalable perovskite scintillators for next-generation medical and industrial imaging.

Abstract

This study presents the fabrication and evaluation of an Optical-guiding Crystal Scintillator (OCS), a structured scintillator that achieves both high spatial resolution and high detection sensitivity in X-ray imaging. Conventional scintillators face a trade-off between these two properties, and structured scintillators have been developed to overcome this trade-off. However, simultaneously achieving fine waveguiding channels with sufficient thickness at bulk scale remains a challenge. The OCS has been proposed to address this issue [1–2]. It has regularly arrayed single-crystal scintillator cores embedded in a low-refractive-index glass cladding. Each core confines scintillation light by total internal reflection. In this work, we grew Tl-doped $Cs_3Cu_2I_5$ (CCI:Tl, n = 1.92) single-crystal cores

through directional solidification from a melt within the 5 μm-diameter channels of a borosilicate glass plate (n = 1.47). Electron backscatter diffraction analysis of the cross-section sample confirmed that each core is a single crystal, and X-ray-excited radioluminescence showed an emission peak at 517 nm, consistent with previously reported values for CCI:Tl single crystals [3]. We evaluated spatial resolution by imaging test charts with a microfocus X-ray tube and calculating the contrast transfer function (CTF). A 500 μm-thick OCS achieved CTF = 35% at 10 lp/mm, compared with 10% for a commercial CsI:Tl columnar scintillator of the same thickness. The OCS maintained spatial resolution over a thickness range of 200 to 700 μm, whereas the commercial scintillator exhibited a sharp decline. Light yield was higher than that of the commercial CsI:Tl columnar scintillator. These results demonstrate that the OCS overcomes the conventional trade-off between spatial resolution and detection sensitivity, opening new possibilities for high-energy X-ray imaging, industrial nondestructive testing, and medical diagnostics.

Abstract
Plastic scintillators are widely used in radiation detection; however, conventional fabrication constrains detector geometry to simple shapes, limiting applicability in complex dosimetry configurations. We report the development of a geometrically flexible plastic scintillator fabricated via stereolithography (SLA) 3D printing, enabling arbitrary-

geometry detector production. The formulation incorporated vinyltoluene (VT, 0–20 wt%) as an aromatic co-monomer, 2,5-diphenyloxazole (PPO, 1–2 wt%) as the primary fluorophore, 1,4-bis(2-methylstyryl)benzene (Bis-MSB, 0–0.01 wt%) as a wavelength shifter, and TPO as the photoinitiator in a commercial acrylate photopolymer host matrix. A post-print resin-dipping technique using the identical formulation improved optical transmittance from 11% to 72%. Main-effect analysis across nine formulations showed that VT at 10 wt% yields optimal optical clarity (~72% at 800 nm), while PPO at 2.0 wt% produces the highest emission intensity at 367–368 nm without concentration quenching. Self-absorption arising from PPO emission–absorption spectral overlap and a host-resin transmission cut-off at 410 nm was identified as the primary optical challenge, establishing Bis-MSB wavelength shifting as essential for light collection beyond the cut-off. Active scintillation was confirmed under Sr-90 via silicon photomultiplier (SiPM) readout, with pulse amplitude 20 times lower than EJ-200. Dosimetric characterization under Cs-137 and Co-60 with EJ-200 benchmarking will be presented.

Energy Spectroscopy Using Tin-Loaded Organic Glass Scintillators of Varying Sizes (#2113)

Erin Neely[1,2], Ethan Schneider[2], Charles Sosa[3], Shaun D. Clarke[2], Sara A. Pozzi[2]

[1] University of Michigan, Department of Applied Physics, Ann Arbor, USA; [2] University of Michigan, Department of Nuclear Engineering and Radiological Sciences, Ann Arbor, USA; [3] Radiation Monitoring Devices, Boston, USA

This work was supported in part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration, award number DE-NA0003920.

Abstract
Organic scintillators doped with heavy metals are promising for nonproliferation work as they combine the low-Z sensitivity to neutrons with the high-Z sensitivity to photoelectric absorption of gammas. Organic glass scintillators (OGS), in particular, are easy to shape and perform almost as well as trans-stilbene in light yield, energy resolution, and pulse shape discrimination. The Detection for Nuclear Nonproliferation Group (DNNG) at the University of Michigan has already completed work on 6-mm and 12-mm cubes of the tin-loaded OGS (or Sn-OGS), finding good agreement between experimental results and MCNP simulations of reasonable fidelity. The measured energy

resolution of the photopeak from the 12-mm Sn-OGS is on the order of 10% and the intrinsic efficiency is visible on a log scale, both with uniform energy-dependent trends. DNNG and RMD have just entered into an agreement to further investigate this material in the form of a 1” x 1” cylinder. We anticipate that similar basic gamma spectroscopy will reveal increased photopeak efficiency and a diminished X-ray escape peak as multiple scatters are more likely in a larger volume; however, the effect of detector volume on energy resolution is unknown. In addition, we hope to present data from Compton coincidence experiments, and begin work with gamma/neutron sources for pulse shape discrimination. This work will also be compared to MCNP simulations.

This research is partly sponsored by the Defense Threat Reduction Agency (DTRA) as part of the Interaction of Ionizing Radiation with Matter University Research Alliance (IIRM-URA) under contract number HDTRA1-20-2-0002.

Abstract

LiquidO detectors stochastically confine scintillation and Cherenkov light around energy depositions by using media with a short optical scattering length. Wavelength-shifting fibers latticed throughout the volume capture the confined light, re-emit it, and transport it to photosensors, creating an optically segmented detector without physical optical barriers. Optical segmentation offers the prospect of effective particle identification and directional reconstruction by using the time of flight, energy deposition, and topology of events that deposit energy at multiple locations in the detector volume. A critical first step toward this capability is a position-sensitive calibration to evaluate detector homogeneity and single-scatter spatial and energy resolution. To achieve this, a four-liter LiquidO prototype detector was constructed and exposed to a collimated Cs-137 source in a tagged Compton scattering configuration. A sodium-iodide detector views the scattering region, providing spatially and energetically constrained event tagging. A Monte Carlo simulation of the experimental geometry models optical photon propagation, light collection, and photosensor noise. Initial measurements indicate a light collection of ~100 photoelectrons per MeV can be achieved in the detector center, and ongoing analysis compares measured and simulated detector responses to quantify the spatial and energy resolution.

Large Scale Lu_2O_3:Yb Ceramics for High-Rate Calorimetry (#2903)

Lakshmi Soundara Pandian[1], Matthias Muller[1], Govinda Adhikari[1], Arthur Kim[1], Suyoung Kim[1], Liyuan Zhang[2], Harvey Newman[2], Patrick Albert[3], Justin Reiss[3], Yimin Wang[1], Jarek Glodo[1]

[1] Radiation Monitoring Devices, Inc., Watertown, USA; [2] California Institute of Technology, Physics, Mathematics and Astronomy Division, Pasadena, USA; [3] Pennsylvania State University, Applied Research Laboratory, State College, USA

This work was supported by the United States Department of Energy through competitively awarded contract number DE-SC0021686. This support does not constitute an express or implied endorsement on the part of the Government.

Abstract

Future high-luminosity collider experiments require scintillators that combine high density, ultrafast response, and strong radiation tolerance. Yb-doped lutetium oxide (Lu_2O_3:Yb) is a promising candidate due to its 9.4 g/cm³ density, sub-2 ns charge transfer luminescence, and light yield near 500 photons/MeV. Due to its very high melting point, Lu_2O_3 is more effectively fabricated through ceramic processing, which enables scalable production of transparent, large volume components for calorimetry and fast timing systems.

Our current effort advances two complementary ceramic routes for producing Lu_2O_3 at detector relevant sizes. In collaboration with PSU/ARL, Field-Assisted Sintering Technology (FAST) approach is being developed to achieve monolithic parts with target dimensions of 2 × 2 × 15 cm³. In parallel, RMD is fabricating 2.5 cm-scale cubes and thin plates using a sinter-plus-HIP process. Optical and scintillation measurements show that thin plates, including 1-inch squares and 14 × 14 × 3 mm³ samples, reach light yields near 500 ph/MeV, while larger cubes currently exhibit reduced output due to limited transparency. All samples emit near 350 nm under X-ray excitation and maintain decay times of approximately 2 ns.

In collaboration with Caltech we also produce Lu_2O_3 plates for the RaDiCAL experiment as potential replacement for LYSO, leveraging the material's high density and ultrafast timing. The combination of fast response, radiation hardness, and scalable fabrication positions Lu_2O_3 ceramics as a strong candidate for next-generation HEP calorimeters and timing detectors. Our results from the latest FAST-processed Lu_2O_3 samples will also be presented at the conference.

Abstract

XEMIS2 is a liquid xenon Compton camera developed at the Subatech laboratory in Nantes, France, designed to demonstrate 3 gamma nuclear imaging on small animals for the first time. This technique exploits the three gamma rays simultaneously emitted by Scandium-44, whose combined detection constrains the emitter position in 3D, enabling a reduction of the injected activity by a factor of 100 compared to conventional Positron Emission Tomography while maintaining equivalent image quality. The detector simultaneously measures two complementary signals: scintillation light, detected by 64 photomultiplier tubes surrounding the liquid xenon active volume, and ionisation electrons, drifted by a 2 kV/cm electric field toward a pixelised anode. Accurate image reconstruction relies critically on the precise calibration of the light acquisition system. The full light calibration chain developed for XEMIS2 is presented, covering the determination of detection thresholds, the photomultiplier tubes gain calibration procedure, and the inter-channel time delay correction validated on both simulation and experimental data.

A Configurable Dual-CDL Sigma-Delta Readout Circuit for Dual-Polarity and High-Precision Signal Detection in CsI: Tl SPECT (#2067)

Xi Zhang, Hamid Sabet

Harvard Medical School, Massachusetts General Hospital, Malden, USA

This work was supported in part by NIH Grant No. R01HL145160 and R01EB034785.

Abstract

Conventional readout electronics for silicon photomultiplier-coupled cesium iodide scintillation detectors are bulky, costly, and difficult to integrate into compact single-photon emission computed tomography systems. Prior sigma-delta modulation charge-to-digital converter implementations are limited to single-polarity operation or require firmware modification for polarity switching. We propose a configurable dual controlled discharging line sigma-delta readout circuit that simultaneously supports dual-polarity readout and high-precision single-polarity charge integration without firmware or hardware modification. The circuit employs a sigma-delta modulator directly integrating silicon photomultiplier charge, with two controlled discharging lines supporting dual-polarity mode for concurrent handling of both signal polarities, and single-polarity mode for fast baseline recovery and precise charge zeroing. Three CsI :Tl crystal configurations were evaluated against a commercial digitizer using Hamamatsu silicon photomultiplier arrays: a small unprocessed crystal with ^{22}Na and ^{137}Cs sources, a monolithic 50×50×8 mm³ crystal with ^{57}Co, and a laser-processed 25×25 pixel array under collimated and flood irradiation. On the small crystal, energy resolutions of 8.49% and 7.47% at 511 keV and 662 keV. On the monolithic crystal, the proposed circuit achieves 7.88% energy resolution at 122 keV versus 13.86% for the CAEN digitizer, a 1.76-fold improvement. On the laser-processed array, a 9% higher peak-to-valley ratio and superior energy resolution are obtained under collimated irradiation, with cleaner pixel separation under flood irradiation. The proposed dual-CDLs sigma-delta readout circuit outperforms commercial digitizers in energy resolution, event rate, and pixel separability across all configurations, offering a scalable, low-cost solution for next-generation SPECT systems.

Abstract

MeV gamma-ray astronomy provides an important observational window for studying cosmic nucleosynthesis, compact objects and high-energy transients. The MeV Astrophysical Spectroscopic Surveyor (MASS) is a 3-D position-sensitive CdZnTe (CZT) detector concept proposed for MeV gamma-ray detection. Its pathfinder payload, MASS-Cube, has been launched on September 5, 2025. To further improve the event reconstruction capability of CZT detectors, this work presents a readout system based on a waveform-sampling ASIC for the future upgrades of MASS-Cube. Preliminary test results show that the readout system can reliably acquire signal waveforms from the CZT detector. With a ^{137}Cs source, FWHM energy resolutions of 1.33% for single-interaction events and 0.69% for single-pixel spectrum were achieved at 662 keV. These results demonstrate the feasibility of the proposed readout chain and provide a foundation for future waveform-based 3-D position reconstruction and imaging optimization.

Abstract

The MALTA2 depleted monolithic active pixel sensor, implemented in 180 nm complementary metal-oxide-semiconductor imaging technology, has demonstrated hit detection efficiencies of up to 98% after neutron irradiation to 3 × 10^{15} 1 MeV n_eq/cm². Measurements at higher fluence motivate further sensor-characterization and test-beam studies, including planned investigations of UHD-modified samples. This contribution presents a new asynchronous oversampling readout developed to support these measurements through more stable sampling of MALTA2 hit signals. The system provides the readout basis for ongoing studies at the CERN Super Proton Synchrotron H6 beam line and future beam-test campaigns at KEK.

Abstract

A 6U CubeSat scheduled for launch in March 2027 will be equipped with a payload for in-orbit charged-particle spectroscopy, requiring on-board signal processing and feature extraction to comply with the narrow-band downlink. To satisfy these requirements, while testing and validating in a space environment a novel technology, an FPGA has been installed implementing the digital logic of the MAIA SoC. The solution is currently entering the testing phase.

MAIA is a fully-programmable mixed-signal System-on-Chip for readout of particle detectors, targeting a 28 nm CMOS node. Each channel integrates selectable analog front-ends a 320 MSps 10-bit waveform sampling ADC, a programmable DSP for continuous-time signal conditioning, a feature extraction engine and four 1.28 Gbps data links. A global trigger unit with real-time pattern analysis capability is integrated as well. The system control is provided by a multi-core cv32e40p RISC-V CPU with radiation-tolerant lock-step operation support and DMA engine, implementing closed-loop real-time control of the signal processing parameters. A chiplet-compatible architecture enables cost-effective channel scaling and connection to external chips. The encapsulation of the UART and JTAG slow-control interfaces on a full-duplex 320 Mbps 8b10b-encoded data link allow remote control of the SoC when integrated in medium or large-scale experiments.

This approach based on high-level of programmability of the signal processing chain can reduce the cost with the respect to producing dedicated front-end ASICs in 110/65 nm for different experiments. All the features of the digital logic of MAIA SoC will be implemented on the satellite FPGA, while the analog front-end and the ADCs will be replaced by the "MIZAR" chip. The payload will be characterized using a particle beam in the next months and the results will be presented at the conference, while the submission of the complete MAIA SoC to the foundry is planned for 2027.

Abstract

The POEMMA Balloon with Radio (PBR) is a NASA's mission to achieve the dual purpose of detecting Ultra-High Energy Cosmic Rays (UHECRs) and performing neutrino astronomy. Planned to operate at stratospheric altitudes, this mission is equipped with two payloads, fluorescence light and Cherenkov light detectors respectively. To detect the latter, a new ASIC was designed in a commercial 65 nm CMOS technology. The Multi-channel Integrated Zone-sampling Analogue-memory based Readout (MIZAR) chip is a 64-channel ASIC developed to read out the signals generated in a tile of Silicon Photo-Multipliers (SiPMs). A single channel is made of 256 cells based on analog memories and working at the sampling frequency of 100 MHz. Each cell allows the local digitization of the events using a configurable Wilkinson Analog-to-Digital Converter (ADC) in the range 8-12 bits. When an event of interest is detected, MIZAR sends out to an FPGA a 64-bit hitmap. This raw information in used as first-level trigger and if it is validated the event is digitized, then the data is serialized through a dedicated Low Voltage Differential Signaling (LVDS) line at 200 MHz in Double Data Rate (DDR). This work describes the scientific context of the PBR mission and the design stages of the MIZAR ASIC. The general results of the test campaign in laboratory are shown, then a focus on the performances in terms of single photo-electron sensitivity and linearity are presented.

Abstract

The China Spallation Neutron Source (CSNS) is undergoing a beam power upgrade to 500 kW. This upgrade requires new detector readout systems for the Energy-Resolved Neutron Imaging (ERNI) instrument. We present CTPX1, a data-driven camera system based on the Timepix4 ASIC, designed to overcome the 80 Mhits/s bandwidth limit of legacy Timepix3 systems. The CTPX1 integrates a custom high-voltage bias supply with a noise floor below 1 mV, a thermoelectric cooling unit that maintains the sensor temperature within 0.1°C, and a Zynq UltraScale+ FPGA-based readout system. The FPGA aggregates sixteen 5.12 Gbps serial links from the ASIC. The system provides a buffered mode for short data bursts up to 81.92 Gbps and a continuous streaming mode up to 64 Gbps via a QSFP+ interface. In high-flux X-ray tests, the system achieved a peak event rate of 1.17 Ghits/s without data loss. During neutron imaging tests at the CSNS BL-20 beamline, using a ^{6}LiF/ZnS:Ag scintillator coupled with an image intensifier, the system obtained a spatial resolution of 55 μm. Furthermore, time-of-flight measurements on austenitic stainless steel successfully identified the Bragg edges corresponding to the expected fcc lattice planes. Quantitative energy calibration using X-ray fluorescence (XRF) also showed a highly linear ToT-to-energy relationship. These results indicate that the CTPX1 meets the high-throughput requirements for energy-resolved neutron imaging, making it a suitable candidate for the ERNI upgrade at CSNS-II. Future work will explore its application at high-flux synchrotron light sources, such as HEPS.

Fast Neutron Spectrometer for Fusion Diagnostics (#3079)

Kartikeya Sharma, Fabrice Retiere

a. TRIUMF, 4004 Wesbrook Mall, Vancouver, British Columbia V6T 2A3, Canada, Vancouver, Canada

This work was supported in part by the Natural Sciences and Engineering Research Council of Canada (NSERC).

Abstract

Advancements in Silicon Photomultiplier (SiPM) performance in recent years have demonstrated success across a broad range of fields, including particle and nuclear physics, Positron Emission Tomography, Light Detection and Ranging technology, Fusion diagnostics, among others. This work develops a time-of-flight (ToF)–based neutron spectrometer using SiPMs coupled to plastic scintillators as a plasma fusion diagnostic tool. A Deuterium-fueled plasma fusion emits 2.45MeV neutrons with an energy spectrum broadened by ion kinematics. The achievable neutron energy resolution of the spectrometer is correlated to the relative uncertainty on the inferred plasma ion temperature, a critical parameter for evaluating plasma performance and viability of the fusion approach. The target relative uncertainty on temperature is below 20%, therefore constraining the neutron interaction time and position resolution within the spectrometer. A two-layer (L1–L2) detector array is in development at TRIUMF. The detector coupled with fast data acquisition is expected to successfully detect neutrons at GHz rate. Timing-Position resolution of the chosen scintillators (Eljen L1: EJ232Q 0.5% Benzophenone doped; L2: EJ230) paired with Broadcom series AFBR-S4N SiPMs is presented as proof of concept in the neutron energy range of interest. A 511keV-gamma source is used to characterize the timing and position response of a single scintillator–SiPM assembly, incorporating the light yield differences between gamma and neutron interactions accounted for via Birks' law. Techniques and results demonstrating time resolution ranging 60 to 120ps with energy in Layer 1 and preliminary work on Layer 2 will be presented.

NSS-18-02

Pixel Size-Induced Visibility Degradation and Its Mitigation for X-ray Dark-Field Baggage Scanners (#2055)

Zhexin Wang[1], Peiyuan Guo[1], Jie Tian[2], Longchao Men[1], Xinbin Li[3], Chengpeng Wu[4,1], Xinchi Ran[1], Zhi Deng[1], Li Zhang[1], Zhentian Wang[1]

This work was supported in part by National Key Research and Development Program of China (No. 2023YFC2605802) and National Natural Science Foundation of China (No. 62227804).

Abstract

X-ray dark-field (DF) imaging enables detection of low-Z scattering materials such as powdered explosives and narcotics, which are indistinguishable in conventional absorption imaging, making it a transformative technology for security screening. However, industrial baggage scanners face an inherent trade-off: high-throughput operation requires large-pixel detectors to capture sufficient photon flux at 160 kV operating voltages, but this causes severe Moiré fringe blurring that fundamentally limits DF sensitivity. In our previous work, we developed a 160 kV dark-field baggage scanner prototype, but found that the 2.7 mm × 3.0 mm large-pixel detectors we used only achieved a fringe visibility of ~7.3% under practical operating conditions, severely limiting DF sensitivity. To address this bottleneck, this study quantitatively investigates pixel size-induced visibility degradation through physics-informed simulations and experimental validation on a benchtop grating interferometry platform. Results confirm the visibility decay trend predicted by the sinc model, and show that a 0.5 mm small-pixel detector achieves ~30% improvement in DF sensitivity for high-energy X-ray dark-field baggage scanners. This work provides critical quantitative guidance for optimizing these systems to improve hazardous material detection.

Three-Dimensional Isotopic Imaging via Portable Neutron Resonance Transmission Analysis (#2122)

Kevin Sanchez, Areg Danagoulian, Nolan I. Kowitt

MIT, NSE, Cambridge, USA

Abstract

Nuclear material safeguards demand portable, isotope specific verification methods capable of operating across diverse deployment contexts. Neutron Resonance Transmission Analysis (NRTA) exploits isotope-specific resonances in neutron cross sections to provide definitive material identification, but portable implementations have been constrained to one-dimensional areal density measurements. Here we present a compact pixelated NRTA system that achieves three-dimensional isotopic imaging through a deuterium-tritium neutron generator, a multi-element GS20 ^{6}Li scintillator array, and Algebraic Reconstruction Technique (ART) algorithms. Systematic benchmarking establishes operational limits: maximum target dimensions of 17.5 × 17.5 × 17.5 cm, stand-off distances up to 17.5 cm, spatial resolution of 2.5 cm, and complete three-dimensional reconstruction within four

hours using eight measurement angles at 30 minutes per angle. Three-dimensional reconstruction of both homogeneous and non-homogeneous tungsten and silver targets is demonstrated experimentally. This system extends portable NRTA beyond one-dimensional assay, enabling field-deployable isotopic imaging previously available only at large centralized neutron facilities.

Neutron diffraction-contrast tomography demonstration using event-based Timepix camera (#2157)

Anton Khaplanov, Ke An, Saurabh Kabra, Shuo Qian, Gergeley Nagy, Chen Zhang

Oak Ridge National Laboratory, NScD, Oak Ridge, USA

This research used resources of the Spallation Neutron Source, High-Flux Isotope Reactor at ORNL. ORNL is managed by UT-Battelle LLC for DOE's Office of Science, the single largest supporter of basic research in the physical sciences in the US.

Abstract
Diffraction contrast tomography is used extensively on x-ray scattering instruments, however, its neutron counterpart has up till now been elusive, in part due to detector limitations. Scintillator-coupled Timepix detectors offer high spatial resolution, event-mode readout, and improved rate capability, making them attractive for neutron scattering and imaging applications. Here we evaluate a LumaCam detector equipped with a TPX3Cam and a ZnO:Zn:6LiF scintillator in a near-field diffraction setup. Scintillation light was focused in a lens onto a 25mm-diameter MCP-based image intensifier. Intensified light was refocused onto a 0.3mm-thick Si sensor with a thin window bonded to a Timepix3 ASIC. Hits were collected in and clusterie to increase position resolution beyond the native pixelation of the ASIC. The detector was placed 10 cm from the sample at 90 degrees to the beam and calibrated using a silicon powder sample. A refractory alloy sample with grains up to 1mm was measured over 180 degrees of rotation. Diffraction spots were assigned to reflections from several crystallographic orientations. By correlating angular separations and relative intensities, 75 grains were identified. Results demonstrate the

feasibility of compact grain-resolved neutron diffraction using Timepix camera technology. Irregular spot shapes indicate sensitivity to grain morphology, however, resolution is smeared by beam divergence. Thus, to fully exploit available detector resolution, shorter sample-to-detector distances are currently being explored. Ongoing work combines near-field diffraction with simultaneous transmission imaging to achieve neutron diffraction contrast tomography by relating diffraction spots to grain locations.

This work was fund by the UKs Science and Technolgies Funding Council, via the DSI: Late-stage commercialisation for time-of-flight neutron spectrometer grant.

Abstract

γ-triggered neutron time-of-flight technique was used to measure fast-neutron spectra from spontaneous fission sources using two EJ-309 liquid scintillator detectors operated in coincidence. Prompt γ-ray detection provided the timing reference for neutron energy reconstruction. Measurements were performed using bare ^{244}Cm and ^{252}Cf sources, together with a moderated ^{252}Cf configuration to investigate scattering effects. Time-of-flight spectra were reconstructed into neutron energy distributions with corrections for detector efficiency and the non-linear time–energy relationship, supported by GEANT4 detector-response simulations. The reconstructed spectra were fitted using Maxwellian and Watt functions. Extracted Maxwellian temperatures were 1.89 MeV for bare ^{252}Cf, 1.41–1.51 MeV for moderated ^{252}Cf, and 1.48 MeV for ^{244}Cm, demonstrating the expected spectral softening caused by moderation. Although systematic deviations from literature values were observed due to detector threshold and efficiency limitations, the method successfully resolved relative differences between source configurations. The results demonstrate the suitability of γ-triggered nToF spectrometry for comparative neutron spectral characterisation.

The authors would like to thank the staff of the FUGEN Decommissioning Engineering Center for their dedicated support during the experiments. This work was supported by JSPS KAKENHI Grant Number JP23K26591.

Abstract

Quantitative evaluation of radioactive contamination is essential for nuclear decommissioning; however, conventional survey methods provide limited spatial information, and conventional Compton cameras lack quantitative imaging capability due to their non-unique source reconstruction, in which the source position spreads into a cone. In this work, we investigate the applicability of an Electron-Tracking Compton Camera (ETCC) [1] to quantitative gamma-ray imaging in a decommissioning environment. The ETCC consists of a gaseous Time Projection Chamber (TPC) as the scatterer and a pixel scintillator array as the absorber. By reconstructing recoil electron tracks in the TPC, the ETCC uniquely solves the Compton kinematics, enabling a one-to-one correspondence between the source direction and the reconstructed image, in contrast to conventional Compton cameras. Measurements were conducted at the Prototype Advanced Thermal Reactor "FUGEN," currently under decommissioning. A ^{60}Co hot spot with a dose rate of approximately 1 μSv/h was successfully identified and imaged, and the dose rate estimated from the ETCC data was consistent with that obtained from a survey meter. In addition, weak ^{60}Co contamination at approximately 0.08 μSv/h, close to the background level and below the sensitivity limit of conventional survey meters, was visualized through direction-resolved analysis. These results demonstrate that the ETCC enables quantitative and sensitive imaging of radioactive contamination and can complement conventional survey methods, with potential to improve the efficiency of contamination assessment and clearance verification in nuclear decommissioning.

Status of the Phase-2 Upgrade of the CMS Outer Tracker (#1573)

Michael Tytgat, On behalf of the CMS Collaboration

Vrije Universiteit Brussel, Inter-University Institute for High Energies, Brussels, Belgium

This work was supported in part by the FWO (grant I001123N) and WEWIS in Flanders/Belgium.

Abstract

The Silicon Tracker of the Compact Muon Solenoid (CMS) is the innermost sub-detector, measuring charged particles produced in high-energy collisions at the Large Hadron Collider (LHC), and is the world's largest silicon tracking system operational today. The High-Luminosity LHC (HL LHC) will increase luminosity by up to an order of magnitude, delivering 3000–4000 fb^{-1} of data with up to 200 simultaneous interactions per bunch crossing. To cope with these extreme conditions, CMS will replace its entire tracking system during the Phase-2 Upgrade. The new tracker will feature enhanced radiation tolerance, finer granularity, and extended coverage, significantly improving tracking efficiency, vertex resolution, and momentum measurement. A key innovation is the inclusion of tracking information at the Level-1 trigger. This is enabled by p_t-modules in the Outer Tracker, each consisting of two closely spaced sensors that correlate hits to identify high-p_t track candidates in real time. The Outer Tracker will comprise over 13,000 such modules, produced worldwide, with a large-scale production underway since 2025. This contribution will detail the Outer Tracker design and the ongoing module production and integration efforts leading up to the installation and commissioning of the new tracker during the upcoming LHC Long Shutdown 3.

Operation and Performance of the ATLAS Liquid Argon Calorimeter During LHC Run 3 (#2118)

Nick Fritzsche, On behalf of the ATLAS Collaboration

CERN, Experimental Physics, Geneve, Switzerland

Abstract

The ATLAS Liquid Argon (LAr) calorimeter provides electromagnetic calorimetry for |η|<3.2 and hadronic and forward calorimetry up to |η|=4.9, playing a central role in the reconstruction and triggering of electrons, photons,

jets, and missing transverse momentum at the Large Hadron Collider. During LHC Run 3, the detector operated under increased instantaneous luminosity and pileup conditions reaching up to approximately 65 interactions per bunch crossing. A major evolution during this period was the commissioning and operation of the Phase-I Digital Trigger readout system based on longitudinally segmented supercells and real-time FPGA processing. The upgraded trigger path provides finer granularity and improved trigger performance compared to the legacy trigger architecture. In addition, the Digital Trigger enables advanced online detector monitoring and demonstrates strong potential for luminosity measurements using statistical properties of digitized supercell signals. Run 3 data show stable detector operation, excellent trigger-readout agreement, and enhanced trigger efficiency for physics objects.

Building the TRISTAN Phase-1 Detector: Characterization of 1000 SDD Pixels (#2158)

Marco Carminati[1,2], On behalf of KATRIN Collaboration

[1] INFN - Istituto Nazionale di Fisica Nucleare, Sezione di Milano, Milano, Italy; [2] Politecnico di Milano, Dipartimento di Elettronica, Informazione e Bioingegneria, Milano, Italy

The author acknowledges support from Politecnico di Milano, INFN (CSN2 KATRIN_TRISTAN Experiment), MPP, KATRIN and KIT.

Abstract
The TRISTAN detector, an array of 9 modules based on monolithic arrays of 166 Silicon Drift Detectors (SDD) pixels is being realized for high accuracy (1 ppm) beta spectroscopy. It will be installed in the KATRIN focal plane by the end of 2026 in order to extend the use of the KATRIN Tritium facility for searching the sterile neutrino in the keV mass range. Each detection module is 4-side buttable and has an area of 4 by 4 cm^2. Here, the progress in detectors assembly is reported. Currently, more than 25 modules have been realized and tested, allowing to select the best 7 modules, out of the final set of 9. They are being characterized in a chamber replicating the operating conditions in terms of vacuum, electric and magnetic fields. Out of the final target value of 1494 pixels, currently a total of 981 pixels are operational, making this system the largest array of spectroscopic SDD detectors ever commissioned. The challenges of this phase are mostly related to production yield and reliability of the complex assembly phase. All pixels show an average FWHM energy resolution below 300 eV for electrons of 20 keV.

Detector Performance Results on the MOSAIX Stitched Sensor Structures for ALICE ITS3 (#2617)

Hartmut Hillemanns, Livia Terlizzi, On behalf of the ALICE Collaboration

CERN, Geneva, Switzerland

Abstract

The ALICE collaboration is currently developing a new vertex detector ("ITS3"), scheduled for installation in 2028 - 2029 during LHC long shutdown 3 to replace the three innermost layers (Inner Barrel) of the existing Inner Tracking System as from Run 4 onwards. ITS3 comprises the use of ultra-thin (down to 50 micrometers) silicon wafers and stitching technologies in 65nm CMOS imaging process , enabling the production of large area (9.8cm x 26.7cm) Monolithic Active Pixels Sensors sensors which will be bent to half-cylindrical shapes of 19, 25.2 and 31.5 mm bending radii for layer 0, 1 and 2 respectively, and supported by carbon foam structures. The very low power consumption of about 40mV/cm^2 allows for air cooling, and the bent shape allows for a minimum of mechanical support using carbon foam only. The very low material budget of less than 0.09% of a radiation length per layer ensures extremely good tracking and vertexing performance. Following an extensive R\&D program for the ITS3, large area stitched prototype structures (MOSAIX) with a final pixel pitch of 20.8µm x 22.8µm, matrix sizes and all other features have been produced and will be tested throughout this year before and after irradiation with TID and NIEL in order to validate the final design for production. In this contribution we present and discuss an overview of detection performance measurements in various test beams.

NSS-19-05

The LHCb PicoCal: a New Radiation-hard ECAL with Picosecond Time Resolution (#2732)

Eduardo Picatoste, on behalf of the LHCb ECAL Upgrade II R&D Group

Universitat de Barcelona, Institute of Cosmos Science of the University of Barcelona, Barcelona, Spain

Abstract

The LHCb Upgrade II program aims to operate at an instantaneous luminosity of up to 1.0×10^{34} cm^{-2} s^{-1}, during the High-Luminosity LHC Run 5, targeting an integrated dataset of 300 fb^{-1}. This ambitious goal requires a complete redesign of the electromagnetic calorimeter (ECAL), leading to the development of the PicoCal detector. The upgrade addresses the challenges of extreme pile-up, high particle densities, and severe radiation levels—reaching up to 1 MGy in the innermost regions—by introducing enhanced transverse granularity and precision timing capabilities at the level of O(10) picoseconds. The PicoCal design combines different technologies optimized for distinct detector regions. The central, high-radiation zones will employ Spaghetti Calorimeter (SpaCal) modules, based on dense absorbers coupled with fast scintillating materials. The
outer regions will be instrumented with upgraded Shashlik calorimeters with fast wavelength-shifting fibers to improve timing performance. Extensive R&D efforts have focused on scintillators, photodetectors, and front-end electronics, with several photomultiplier tube (PMT) candidates evaluated for their timing precision and radiation tolerance. Prototype modules of both SpaCal and Shashlik technologies have been successfully designed, constructed, and tested. Test beam campaigns demonstrate that the calorimeter achieves an energy resolution with a stochastic term of about 10% sampling contribution and 1% constant term, while timing resolutions better than 20 ps are achieved at high energies across different scintillator options. In parallel, the SPIDER ASIC prototype has been validated in beam tests, achieving timing performance comparable to standard digitizer-based readout systems. These results collectively demonstrate that the PicoCal concept meets the stringent performance requirements of LHCb Upgrade II, ensuring precise energy and time measurements
under extreme HL-LHC conditions.

digital SiPMs for future RICH detectors (#2857)

Prabhleen Singh[1], Rok Dolenec[2], Claudio Bruschini[1], Edoardo Charbon[1]

[1] EPFL, STI IEM AQUA, Neuchatel, Switzerland; [2] Jozef Stefan Institute, Experimental Particle Physics Department, Ljubljana, Slovenia

Abstract

Planned upgrades to Ring Imaging Cherenkov (RICH) detectors in the LHCb, Belle II, and ALICE 3 high energy physics experiments require photodetectors capable of single-photon detection at high event rates and neutron fluences up to a few 10^{13} 1-MeV equivalent/cm². The spadRICH project develops a CMOS-based single-photon avalanche diode (SPAD) array optimized for radiation hardness and cryogenic operation to meet these requirements.

This paper presents a decision-maker (DM) circuit architecture for use in digital silicon photomultiplier (dSiPM) readout. The DM identifies the first-firing SPAD along with its address among competing channels and disables both the winning and losing SPADs immediately after the decision, thus suppressing subsequent avalanches. Combined with fast quenching, this reduces afterpulsing and lowers power consumption in multi-channel readout — critical for operation in high-radiation cryogenic environments. The DM can be cascaded into a binary tree topology to implement full dSiPM functionality. dSiPMs with varying aspect ratios and SPAD sizes are fabricated in the GlobalFoundries 55 nm BCDLite® process. In addition to dSiPMs, we have also implemented analog SiPMs (aSiPMs) to compare the advantage of its high fill factor with selective deactivation of SPADs and time-gating features of dSiPMs in high radiation environments.

Development and validation of the Forward Feature Extractor Prototype for high-speed data processing in the ATLAS L0Calo trigger systems

(#2816)

ATLAS Collaboration ATLAS Collaboration, On behalf of the ATLAS Collaboration

ATLAS Collaboration, CERN, Geneva, Switzerland

Abstract

We present the development and validation of the Forward Feature Extractor (fFEX) prototype module, a key component of the ATLAS Experiment's Phase-II Level-0 Calorimeter (L0Calo) trigger system for real-time event filtering and feature extraction. The prototype module has been produced and validated through an extensive test campaign. Hardware validation demonstrates stable power delivery, full main-board core functionality, reliable FPGA operation including high-speed transceivers and bit-error-rate tests at 25.8 Gbps per link, robust clock distribution including jitter cleaners and fanout stages, and complete control and monitoring functionality. In addition, integration tests with other ATLAS Phase-II subsystems have been carried out and the results are reported, confirming interoperability and being suitable for operation within the experiment's complex trigger and data-acquisition architecture. The system achieves a total throughput of 2.5 Tbps per main FPGA, including real-time processing and data-handling operations. On the firmware side, a modular design has been implemented, comprising the infrastructure layer, including an implementation of the Interlaken protocol (Core1990) and a simple-packet based protocol called IPBus, the readout firmware, and the algorithmic firmware. In this article, particular emphasis is placed on the readout path and the handling of multiple data types and trigger objects, including the formatting, error-correction and flow-control aspects. The algorithmic firmware supports the identification of jets, electromagnetic clusters, and hadronic tau candidates, and the calculation of global quantities such as missing transverse energy (MET). These results demonstrate the technical readiness of the fFEX prototype for further system-level integration, timing and performance studies.

Lessons Learned from the sPHENIX Experiment (#1595)

Martin L. Purschke

Brookhaven National Laboratory, Physics, Upton, USA

for the sPHENIX collaboration

Abstract

The sPHENIX experiment at the Relativistic Heavy Ion Collider (RHIC), and RHIC itself, concluded their beam operations on Feb. 6, 2026. RHIC and the experiments are now being decommissioned to begin construction of the Electron-Ion Collider. This marks the end of 25 years of Heavy-Ion and polarized proton-proton Physics at the facility.

sPHENIX was designed as a high-rate detector optimized for precision measurements of jets, heavy flavor, and quarkonia in Relativistic Heavy-Ion collisions. Following a successful commissioning phase, the experiment collected high-quality data in p-p , Au-Au, and O-O collision systems.
To summarize our key performance numbers:

- The sPHENIX DAQ system has exceeded the design event rate of 15 kHz
- We were able to sustain a DAQ data rate of more than 70 GB/s
- We accumulated just under 300 PB of data on tape with beam, and crossed the 300 PB threshold with the post-shutdown calibration data.We present key lessons learned from the design, commissioning, and operation of the sPHENIX data acquisition system. We also briefly discuss ongoing analysis efforts and the anticipated physics legacy of the sPHENIX program.

NSS-20-03

Architecture and Performance of a Versatile Trigger, Tracking and Readout System for Particle Detector Beam Tests (#1917)

Liliana Congedo[1], Roberta Pillera[1], Davide Cerasole[1,2], Giuseppe De Robertis[1], Leonardo Di Venere[1], Fabio Gargano[1], Mario Giliberti[1,2], Francesco Licciulli[1], Antonio Liguori[1,2], Rocco Liotino[1,2], Pierpaolo Loizzo[1,3], Francesco Loparco[1,2], Leonarda Lorusso[1], Mario Nicola Mazziotta[1], Nicola Nicassio[1,2], Giuliana Panzarini[1]

Abstract
This work presents the development and validation of a Trigger, Tracking, and Readout System for the beam test characterization of novel particle detectors, designed to address the challenges of providing precise reference tracking for event reconstruction while integrating heterogeneous front-end electronics. The system combines a scalable tracking apparatus based on scintillating fibers coupled to Silicon Photomultipliers, a Centralized Control Unit for trigger generation and system synchronization and a modular readout architecture based on Field Programmable Gate Arrays. A dedicated software platform provides unified control of data acquisition, configuration and monitoring, ensuring efficient system operation. The overall design approach relies on hardware modularity and the use of commercial components, complemented by adaptable firmware and software to interface multiple detector technologies with minimal customization effort. The system has been validated during beam test campaigns of a Ring Imaging Cherenkov detector prototype for the future ALICE3 experiment, foreseen at the High-Luminosity Large Hadron Collider. The results demonstrate accurate event reconstruction capability, with a data matching efficiency among independent readout boards exceeding 99%, ensuring reliable synchronization

across different subsystems. In addition, a time resolution at the level of a few tens of picoseconds have been measured, highlighting the remarkable timing performance of the system and its suitability for the characterization of high-precision timing detectors. The results confirm the effectiveness of the proposed system as a cost-effective, flexible, scalable, and portable solution that can be readily employed for the development and beam test validation of future particle detectors based on a wide range of technologies.

TD-Link: A Daisy-Chain Optical Architecture for Integrated Data Readout and Deterministic Timing Distribution in Large-Scale Detector Systems (#1971)

Andrea Abba[1], Valentina Arosio[1], Gianluca Becuzzi[2], Matteo Bianchini[2], Francesco Caponio[1], Stefano Carsi[1], Alberto Cusimano[1], Camilla Maggio[2], Annalisa Mati[2], Daniele Ninci[2], Andrea Picchi[2], Carlo Tintori[2], Yuri Venturini[2]

[1] Nuclear Instruments SRL, Lambrugo, Italy; [2] CAEN SPA, Viareggio, Italy

Abstract
TD-Link is a versatile optical communication architecture combining high-throughput data readout and sub-nanosecond timing synchronization over a single optical fiber for large-scale detector systems. The protocol adopts a multidrop daisy-chain ring topology connecting one Data Concentrator to up to sixteen FERS front-end boards per link, with multiple independent links per concentrator, enabling scalable instrumentation with reduced optical infrastructure. Operating at 3.25 Gb/s, TD-Link transports data, synchronization, and control traffic within the same serial stream through a token-based protocol minimizing per-hop latency and supporting packet fragmentation. The synchronization system distributes a global time reference (T0) with deterministic latency. On the concentrator, transmitter lane alignment exploits the half-full condition of the transceiver elastic buffer as a 1-bit phase detector. A firmware state machine iteratively adjusts the TX phase interpolator until the write-to-read pointer difference reaches half the buffer depth, locking the lane to a deterministic phase condition. A Digital Dual Mixer Time Difference (DDMTD) circuit is used only for inter-concentrator synchronization, compensating the phase offset between the recovered transceiver clock and the FPGA fabric reference clock.
On FERS boards, recovered clocks are cleaned through an external zero-delay PLL and retransmitted

downstream, preserving phase coherence along the daisy chain. Deterministic T0 latency is ensured by disabling elastic buffers and routing timing signals through calibrated delay paths.
Experimental validation with CERN PicoTDC-equipped FERS boards demonstrates a synchronization sigma of 6 ps for boards sharing the same coaxial clock reference and below 25 ps for boards connected to different concentrators. The performance remains stable across repeated power cycles, confirming the robustness of the phase alignment strategy.

NSS-20-05

Design and test of a readout board for the ePIC dRICH detector (#2620)

The authors wish to thanks INFN Bologna, Ferrara and Torino for funding the project.

Abstract
This paper presents the design of a board named RDO (ReaDOut module) which is the main building block of the readout system for the dual-radiator RICH (dRICH) of the ePIC experiment at the future Electron-Ion Collider (EIC). The main purpose of the board is to provide an interface towards the front-end ASICs (the ALCOR chips) and towards the main data acquisition system (the FELIX boards) through a high-speed optical link based on the CERN VTRx+ optical transceiver. Among the many requirements, the board needs to fit a very limited size and must withstand a moderately hostile radiation environment. The board has already been used in a test-beam at CERN and it has also undergone irradiation tests of its main components: the most significant results will be presented and discussed.

Abstract

The LHCb Phase-II electromagnetic calorimeter upgrade, known as PicoCal, requires new radiation-tolerant front-end electronics capable of providing precise energy and timing measurements under the demanding conditions expected after the High-Luminosity LHC upgrade. Two dedicated ASICs are being developed for this purpose in TSMC65 technology: ICECAL65 for energy measurement, and SPIDER for picosecond timing reconstruction. ICECAL65 follows the scheme in the ASIC currently used in the LHCb calorimeter. Nonetheless, it adopts a dual-gain architecture with time-interleaved subchannels to achieve 12-bit precision over a wide dynamic range while eliminating dead time between input samples. The analog chain integrates configurable shaping, tunable integration, and high-speed track-and-hold stages synchronized through an integrated PLL. Post-layout simulations indicate a power consumption of 40 mW per channel, output noise compatible with 12-bit precision, linearity errors below 1%, and spillover below 2.5%. SPIDER is a waveform digitizer ASIC dedicated to ultra-fast timing measurements. Based on the Waveform Time-to-Digital Converter concept, it samples detector signals inside programmable windows synchronized with the 40 MHz LHC clock. The architecture combines analog memory banks, embedded discriminators, DLL-based timing control, and massively parallel Wilkinson ADC conversion. Configurable sampling frequencies from 1.6 to 20 GS/s enable timing resolutions well below 10 ps rms. While post-layout simulations of ICECAL65 are still pending verification, first measurements of SPIDER_V0 demonstrate a Time Difference Resolution of 7.13 ps rms between two asynchronous pulses, corresponding to a single-channel precision close to 5 ps. Together, ICECAL65 and SPIDER provide a complete front-end solution for the PicoCal upgrade and represent a promising platform for future fast-timing detectors in high-energy physics.

Design and Performance of the Fermilab Constant-Fraction Discriminator (FCFD) Readout ASIC for ePIC Barrel Time-of-Flight Detector (#2797)

Artur Apresyan[1], Cristinel V. Gingu[1], Datao Gong[1], Neha S. Kharwadkar[1], Sergey Los[1], Cristian Pena[1], Chinar Syal[1], Shuoxing Wu[1], Si Xie[1,2], Todd Zenger[1], Thomas Zimmerman[1]

[1] Fermi National Accelerator Laboratory, Batavia, USA; [2] California Institute of Technology, Pasadena, USA

Abstract

We present the design and performance of the FCFD1.1 constant-fraction discriminator ASIC for precision timing detectors based on AC-LGAD sensors. The chip, implemented in 65 nm CMOS, achieves ~ 40 ps time resolution and 15-20 μm spatial resolution in beam tests, with full detection efficiency over the sensor surface. The design integrates on-chip time-walk correction, reducing reliance on offline calibration. Building on this result, we introduce FCFD1.2, a six-channel full-chain prototype for AC-LGAD readout. Each channel includes a constant-fraction discriminator, an ADC block, and a self-calibrated TDC, while the six channels share a common readout block that packs the data into frames and outputs them through a serializer. The chip was submitted in April 2026, and preliminary test results are expected to be presented at the conference. Its architecture targets ~ 45 ps overall timing resolution, with less than 10 ps contribution from the internal electronics, enabling scalable, low-power timing readout for future detector systems.

LDMX Timing Distribution and Data AcquisitionSystem (#2940)

Benjamin A. Reese[1], Christos Bakalis[1], Ryan Herbst[1], Timothy K. Nelson[1], Lauren Tompkins[2], Elizabeth Berzin[2], Matt Weaver[1]

[1] SLAC National Accelerator Laboratory, Menlo Park, USA; [2] Stanford University, Stanford, USA

Abstract

The Light Dark Matter eXperiment (LDMX) will search for sub-GeV dark matter with a fixed-target missing-momentum technique requiring time-aligned detector data from several independent subsystems, including the Trigger Scintillator, Silicon Tracker, Electromagnetic Calorimeter, and Hadronic Calorimeter. This work presents the LDMX trigger and data acquisition (TDAQ) system for timing distribution, fast control, and event tagging. The

central timing node is implemented on an APx ATCA board originally developed for CMS. It receives the LCLS-II accelerator timing stream and recovers the 185.714 MHz timing clock and timing frames. Firmware combines accelerator pulse identifiers, run state, and Global Trigger decisions into fixed-latency 3.714 Gbps PGP Fast Control (PGPFC) messages for endpoints. Timing Messages carry a 56-bit pulse ID, 4-bit run state, and state-changed flag. Readout Request (RoR) messages, analogous to Level-1 Accept triggers, carry pulse ID and a 6-bit bunch count. Endpoints recover the fast-control clock, derive a 37.14 MHz bunch clock, align RoRs to bunch boundaries, and write the common timestamp into DAQ event headers. Common firmware blocks provide fast-control reception and event formatting for subsystem designs, enabling offline alignment and future real-time event building. Run states support trigger-data alignment and RoR-latency calibration before physics. In a 2025 beamline test at End Station A at SLAC, this architecture acquired coherent data at 10 Hz for up to 12 hours with aligned contributions from participating reduced-scale detector-subsystem slices.

Development of a Cost-Effective PCCT Detector Based on Sub-Millimeter EQR SiPM and LYSO Array with High Count Rate and Adequate Energy Resolution (#6)

Yongqiang Yan[1], Mingyue Huang[1], Xu Zhang[1], Kun Liang[1], Ru Yang[1], Dejun Han[1,2]

[1] Beijing Normal University, school of Physics and Astronomy, Beijing, China; [2] Beijing Normal University, Applied Optics Beijing Area Major Laboratory, Beijing, China

Abstract

Among the detector candidates for clinical photon-counting CT (PCCT), SiPM-based fast-scintillation photon-counting detectors (PCD) represent a cost-effective solution. However, their practical implementation is constrained by the incompatible trade-off between count-rate capability and energy resolution. To address this limitation, we developed a scintillation PCD designed to achieve both high counting rate and improved energy resolution. The detector consists of a 26-channel pixelated LYSO scintillator array coupled to an epitaxial-quenching-resistor (EQR) SiPM array with a 0.5-mm pixel pitch and 15-μm microcells. Benefiting from the EQR architecture, the SiPM pixels exhibit a fast recovery time of 3.2 ns, a 64% fill factor, and a photon detection efficiency exceeding 40% at 420 nm. A multi-channel FPGA-based photon-counting readout circuit with per-channel pole-zero cancellation was developed to suppress signal tailing and mitigate pulse pile-up. This PCD achieved a maximum count rate of 46.3 Mcps/mm² while maintaining an energy resolution of 33.7% at 59.5 keV. The spatial resolution of 1.86 lp/mm (537 μm) was achieved under 120-keV X-rays, which agreed closely with the 0.5-mm physical pixel pitch of the detector. A more sophisticated PCD based on a 64-channel EQR SiPM array with 0.25-mm pixel pitch and 10-μm microcells, coupled to a corresponding pixelated LYSO scintillator array, will also be presented. Those results indicate that the proposed scintillation PCD is a promising cost-effective candidate for clinical PCCT applications.

Abstract

We report on the development and characterisation of innovative Backside-Illuminated Silicon Photomultipliers (BSI-SiPMs) within the INFN IBIS and IBIS_NEXT projects. The BSI architecture relocates the photon entrance window to the back side of the device, enabling high fill factor and improved photon detection efficiency while preserving compatibility with advanced front-end electronics integration, and offering the potential for enhanced sensitivity in the VUV region.

A preliminary experimental campaign has been performed on partially processed BSI prototype devices, including electrical characterisation over a wide temperature range, dark count rate measurements, irradiation studies, annealing tests, and timing performance evaluation using both pulsed laser excitation and minimum ionising particles (MIPs) at CERN.

Irradiation up to 10^9 n_{eq}/cm^2 results in an increase in dark count rate. Preliminary annealing studies show recovery of dark current by nearly one order of magnitude. Timing measurements yield resolutions of order ~100 ps, demonstrating the potential of BSI-SiPMs for fast timing applications in high-energy physics.

Abstract

Digital silicon photomultipliers (SiPMs) are being developed to circumvent many of the shortfalls inherent to analog SiPMs and their associated readout electronics. We design 3D-integrated digital SiPMs, called Photon-to-Digital Converters (PDCs), to simultaneously optimize the photosensitive area, remove analog noise contributions, and embed signal processing. With a low-power-optimized readout architecture providing high timing resolution, we demonstrate fully digital measurement approaches and their benefits across multiple fields, including time-of-flight medical imaging and neutron imaging. Leveraging the high-timing precision of the PDC through pulse shape discrimination, the components of an LGSO (Fast/Slow) phoswich scintillator assembly are precisely classified, while maintaining the expected energy resolution for the scintillators irradiated with calibration isotopes such as a 68Ge source. Coincidence timing resolution is also assessed for this configuration. These results position PDCs as great candidates for depth-of-interaction reconstruction in PET imaging, ToF measurement in CT imaging, and particle identification in neutron imaging.

Abstract

Segmentation of the SiPM active area into smaller, independently read out elements is one of the most promising routes to improve the single-photon time resolution (SPTR) required by next-generation time-of-flight PET systems. We report on Single-Cell Access through-silicon vias (SCA-TSVs), a custom TSV technology under development at Fondazione Bruno Kessler (FBK), Trento, and applied to the NUV-HD-MT SiPM platform. SCA-TSVs exploit the deep-trench isolation (DTI) already present in this technology to physically separate and independently access each SiPM microcell from the backside, with essentially no loss of fill factor. A backside redistribution layer (RDL) can then regroup microcells with an arbitrary segmentation level, according to application requirements. The first implementation targets the DIGILOG project, where a 3 × 3 mm² SiPM with 50 µm cells is segmented into 3 × 3- or 6 × 6-cell clusters, referred to as microSiPMs. These units are designed to be read out independently by a matched ASIC developed at EPFL and connected through chip-to-chip 3D integration. This approach preserves the SPTR of a single SPAD, approximately 25 ps FWHM, while avoiding the complexity of full single-cell readout. The first SCA-TSV learning cycle (LC1) required modifications to the original NUV-HD-MT technology, mainly an increase of the DTI depth beyond 20 µm. Front-side characterization showed that the timing performance was preserved. The first backside integration runs also revealed a reduced TSV yield. The analysis identified both layout-related and backside-process-related limitations, which are being addressed through optimized LC1 backend process splits and in the second technology learning cycle (LC2). The presentation will discuss the SCA-TSV concept, LC1 fabrication and characterization results, and the latest LC2 developments toward 3D-integrated microSiPM/ASIC chips for fast-timing applications.

Abstract

Precise detection of elementary particles such as neutrinos, gammas, or electrons in an unsegmented scintillating volume requires three-dimensional tracking with sub-nanosecond timing resolution [1], [2]. However, conventional detectors based on analog silicon photomultipliers are inherently constrained by trade-offs between spatial resolution and scalability, making them less suitable for large-scale implementations [3]. To overcome these limitations, CMOS single-photon avalanche diode (SPAD)-based detectors have emerged as a promising alternative for high-resolution particle detection [4], [5]. Here, we propose a dedicated large-format SPAD array sensor fabricated in 110 nm CMOS image sensor (CIS) technology, targeting both high timing precision and scalability. The sensor incorporates a high photon-detection-efficiency SPAD pixel architecture that triggers time-to-digital converters (TDCs) in an event-driven manner with a resolution of 200 ps to detect sparse photons generated by probabilistic events such as particle interactions. All TDCs are synchronized with a global reference clock distributed through an on-chip phase-locked loop, ensuring precise timing alignment across the entire sensor array. Furthermore, a tunable clock shifting feature is implemented to compensate for clock skew in multiple-chip operation. As a result, this chip serves as a fundamental building block for a scalable, multi-chip tiled detector system in which all timing information is globally synchronized, enabling future large-scale, high-resolution particle tracking applications.

Abstract

Single-photon avalanche diodes (SPAD) produced in CMOS technologies are increasingly being considered as photodetector candidates for future Ring imaging Cherenkov (RICH) detectors. CMOS SPAD based sensors with integrated electronics can be designed and optimized specifically for RICH detector applications, making it easier to achieve the high photon detection efficiency, excellent single photon timing resolution and hardness to neutron radiation as required in the planned high energy physics experiments. To help guide the design of first digital SiPM targeting RICH detector applications being developed in the spadRICH project, existing single SPADs as well as a 144x32 SPAD array were studied in terms of their operation after neutron irradiation. Dark count rates were measured for neutron irradiation as high as 10^{12} 1-MeV neutron equivalent/cm^2. Thermal annealing and operation at temperatures down to liquid nitrogen were explored. In terms of cryogenic operation, afterpulsing probability and behavior of the photon detection efficiency were also studied. Simulations were used to assess the possible performance of microlenses specifically for the highly collimated Cherenkov photon light as expected in the upgraded LHCb RICH detector.

Abstract

Single-photon avalanche diodes (SPADs) fabricated in a 110 nm CMOS technology were irradiated with neutrons, protons, and electrons over a range of fluences up to 10^{11} 1 MeV neutron-equivalent cm^{-2}. The dark count rate (DCR) evolution was systematically characterized as a function of displacement damage dose; online monitoring during neutron and proton irradiation allowed individual scattering events and short-term annealing dynamics to be resolved at the single-pixel level, providing direct insight into defect formation and recovery. Statistical characterization of the DCR distributions reveals that the average DCR alone is insufficient to describe radiation-induced degradation in SPAD arrays: the particle type critically determines both the magnitude and spatial uniformity of damage. These differences reflect distinct defect morphologies - clustered damage for hadrons, isolated point defects for electrons - a key aspect not captured by NIEL scaling alone.

First developments of NUV-DJ SiPM arrays forcryogenic operation for the LHCb SciFi tracker Upgrade II (#2830)

Carina Antonia Trippl[1], Fabio Acerbi[1], Esteban Curras Rivera[2], Guido Haefeli[2], Oscar A.M. Villarreal[1], Shuqi Sheng[2], Alberto Gola[1]

[1] Fondazione Bruno Kessler, CRS, Trento, Italy; [2] École Polytechnique Fédérale de Lausanne, LPHE, Lausanne, Switzerland

Abstract

This work presents the first cryogenic performance evaluation of the novel Near-Ultraviolet Deep-Junction (NUV-DJ) SiPM technology developed by Fondazione Bruno Kessler (FBK). By relocating the high-electric field region deeper within the substrate, the NUV-DJ architecture achieves a state-of-the-art photo-detection efficiency of approximately 70% at 420 nm and a timing resolution of 60 ps FWHM at room temperature with a 4 x 4 mm^2 SiPM. We report on a comprehensive dark characterisation of these sensors from 300 K down to 77 K, extracting the activation energy (Ea) to identify dominant carrier generation mechanisms, and evaluating the stability of correlated noise and gain. These studies serve as a foundation for a new dedicated production run for the LHCb Scintillating Fibre (SciFi) Tracker Upgrade II, in collaboration with EPFL, featuring custom 0.4 mm2 geometries and advanced afterpulsing suppression. The main goal is to assess whether the enhanced blue-green sensitivity of NUV-DJ, which is advantageous for the readout of irradiated blue-emitting scintillating fibres, can be combined with radiation tolerance and stable cryogenic operation at liquid-nitrogen temperature.

The project was funded by the U.S. Department of Energy, National Nuclear Security Administration, Office of Defense Nuclear Nonproliferation Research and Development.

Abstract

Spectral templates used for radiological anomaly detection and isotope identification are most commonly derived from simulation, yet real-world source encounters are subject to a diversity of shielding configurations, scattering geometries, and encounter dynamics that simulation does not fully capture. The PANDAWN sensor network — fourteen statically deployed, multi-modal radiological detection nodes distributed across Chicago, IL — provides a unique opportunity to learn spectral templates directly from real-world data. In this talk, we present the application of regularized Non-Negative Matrix Factorization clustering to anomalous gamma-ray spectra, which recovers multiple spectrally distinct templates for nuisance isotope encounters observed across the network, each corresponding to physically interpretable differences in source attenuation and encounter geometry. Examining how these cluster components trigger isotope identification during known source encounters reveals distinct temporal patterns, further demonstrating that the learned templates capture meaningful structure in the real-world encounter environment. We will discuss what these results reveal about source encounters across the network, present an assessment of template transferability across nodes, and examine how developing a taxonomy of data-driven source templates of this kind can improve detection and isotope identification performance.

Spatially-derived Enhancement of Time-domain PSD and Spectroscopy Measurements (#1991)

Patrick M. Collins-Price, Ioannis Tsitsimpelis, Michael D. Aspinall, Malcolm J. Joyce

Lancaster University, Engineering, Lancaster, UK

Abstract

Geometrical event removal (GER) via a position-sensitive multianode photomultiplier tube (MAPMT) is used to enhance mixed-field pulse-shape discrimination (PSD) in an organic EJ-276 scintillator and gamma spectroscopy peak-to-continuum ratio in a CeBr3 crystal scintillator. Significant (~21.3%) improvements in PSD figure-of-merit (FoM) are shown without the need for an energy cut-off, allowing for real-time spectrum-agnostic enhancement of time-domeain PSD methods. This allows greater separation of the neutron and gamma plumes at low energies without the need for a low-energy cutoff, thereby preserving the ability to measure across the full range of neutron spectra. The position sensitivity of the detector has also been exploited to create 2D flux map images of gamma fields attenuated through various lightweight 3D-printed collimators, and to identify the isotope and relative direction of individual point gamma sources in a multi-isotope combined field.

Impact of Air Activation on Tritium Monitoring in Fusion Energy Systems (#2627)

Shaun D. Clarke[1], David Breitenmoser[1], Michael Y. Hua[2], Sara A. Pozzi[1]

[1] University of Michigan, Department of Nuclear Engineering & Radiological Sciences, Ann Arbor, USA; [2] Helion Energy, Inc., Everett, USA; [3] Helion Energy, Inc., Everett, USA

This work was supported in-part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration award number DE-NA0003920.

Abstract

Robust tritium monitoring is essential for fusion energy systems, where rapid detection of low-level airborne releases is needed to support safe operation and accident response. However, intense neutron fields in fusion environments activate surrounding air and produce radioactive products that can contribute beta, gamma-ray, and X-ray backgrounds, complicating tritium detection. In this work, we investigate the impact of air-activation products on a proposed tritium detection concept that combines a thin plastic scintillator beta cell with a surrounding NaI(Tl) anti-coincidence shield. The plastic scintillator provides sensitivity to the low-energy beta particles from tritium decay, while the NaI(Tl) detector enables rejection of coincident photon backgrounds. Monte Carlo simulations were performed using MCNP6 to estimate the detector response to tritium and relevant air-activation radionuclides, including beta emitters such as 13N, 14C, 39Ar, 39Cl, and 41Ar, as well as associated gamma-ray, X-ray, and bremsstrahlung contributions. A 1.3-mm-thick plastic scintillator cell was modeled to match commercially available thin-walled beta cells used in radioxenon detection. Preliminary results show that several air-activation products produce signals in the same low-energy region as tritium and may represent important background contributions, particularly when gamma rays are not detected in coincidence. Subsequent simulations will be performed using the MCNPX-PoliMi code to accurately treat the correlated detection of electrons and photons in the plastic and NaI(Tl) cells.

Attention-Biased Additive Point Source Localization (#2925)

Emil Rofors, Brian J. Quiter, Victor Negut

Lawrence Berkeley National Laboratory, Berkeley, USA

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Berkeley National Laboratory (LBNL) under Contract DE-AC02-05CH11231. The project was funded by the U.S. Department of Energy, National Nuclear Security Administration, Office of Defense Nuclear Nonproliferation Research and Development.

Abstract

We present Attention-Biased Additive Point Source Localization (ABAPSL), a fast reconstruction method for localizing multiple radioactive point sources from mobile gamma-ray measurements. The method extends our prior gridded multi-source localization work, which found sources one at a time and added confirmed sources into a growing background model. ABAPSL instead re-fits all active sources at each reconstruction while using an attention metric to place fine test points only where the data support high sensitivity or high source likelihood. This provides local 10cm-scale refinement without requiring a uniformly fine grid over the full survey area. We also introduce multi-resolution spatial measurement binning, replacing fixed time bins with trajectory-aligned spatial bins that remain fine near candidate sources yet are coarser in background-dominated regions. The resulting system matrix is small enough for online reconstruction on mobile computers such as the onboard compute used in a Localization and Mapping Platform (LAMP) system. We demonstrate the approach with simulations around multiple radioactive point sources, with LAMP measurement validation to follow.

VETTR: A Robotic Landmine Detection System via Associated Particle Imaging (#2957)

Ryan Pavlovsky, Patrick Freeman, Victor Goicoecheaca, Seth DuBridge, Justin Ellin, Justin Oshiro, Brooke Bilyeu, Erika Suzuki, Andrew Haefner, Kai Vetter

Gamma Reality Inc, Berkeley, USA

Abstract

Gamma Reality Inc has developed and demonstrated, to our knowledge, the first robotic deployment of Associated Particle Imaging (API) for the application of rapid-assessment, detection and 3D imaging of buried landmines. We utilize a deuterium-tritium (DT) reaction to generate momentum-tagged neutrons, at rates up to 5E8 n/s, that

stimulate characteristic gamma-ray emissions. The result is 3D voxel-spectral information that we combine with contextual sensed scenes, via 3D LiDAR, providing a centimeter resolution map of isotopic compositions within a specific scene. There are many non-destructive assay applications for such a system, however we identify landmine detection as our first application space. Modern landmine detectors are sensitive to secondary characteristics of mines, such as low mass-metal content within the mines, and struggle with false-positive probabilities. Our method targets the primary characteristics of mines, which has the potential for a very large reduction in false positive rate compared to current methods, which can be 30 to 1 or often worse. In this paper we present results of our field demonstrations and domestic tests, where we identify surrogate mine materials constructed of ammonium nitrate and carbon against common background and nuisance objects (organic materials, metal objects, & etc). We present results for 20 min, 5min and 1min detections over mine surrogates in soil. We will also present the results of field-testing over TNT and other explosive fills in replica casings.

Abstract
Dosimetry under the high dose-rate conditions is required such as internal survey of the Fukushima Daiichi Nuclear Power Plant for the decommissioning. We have developed a dose-rate monitor consisting of optical fiber and scintillators. Since the optical fiber has lower collection efficiency of the scintillation photons compared to that of direct contacting between a scintillator and photomultiplier tube, higher light output was required. Moreover, long emission wavelength of over 650 nm is required to obtain sufficient sensitivity. Cr-doped oxides are expected to have emission wavelength in the red or infra-red region, and garnet crystals can be optimized the emission wavelength by changing crystal fields. Thus, we focused on Cr-doped $(Y, Gd)_3(Al, Ga)_5O_{12}$ materials as red oxide scintillators, and $Gd_3(Ga_{0.995}\ Cr_{0.005})_5O_{12}$ (Cr:GGG) single crystals grown by the micro-pulling-down method had an emission wavelength of Cr:GGG was 731 nm, which achieved the emission goal. Using this Cr:GGG sample we

have developed the real-time dose monitor, and such system was found to operate the survey even under the high dose rate of around 1 kSv/h. Moreover, we evaluated the absorption dose with different gamma-ray energies with geant4 (gamma-ray energy response), and the result was consistent with gamma-ray irradiation test with ^{137}Cs and ^{60}Co sources.

A Timing ASIC for Large-area SiPM Readout with Channel Delay Compensation (#2660)

Yi Fu, Weihao Wu, Mingxin Wang

Shanghai Jiao Tong University, Institute of Nuclear and Particle Physics, School of Physics and Astronomy, Shanghai, China

This work was supported by National Key R&D Program of China (Grant No. 2023YFA1606203) , National Natural Science Foundation of China (Grant No. 12575197), Shanghai Pilot Program for Basic Research — Shanghai Jiao Tong University (Grant No. 21TQ1400218).

Abstract

The detector of TRopIcal DEep-sea Neutrino Telescope (TRIDENT) will use large-area silicon photomultiplier (SiPM) arrays combined with photomultiplier tubes to boost photon detection efficiency and pointing capability. An application-specific integrated circuit (ASIC) is being developed to aim at high-resolution time measurement of large-area SiPM arrays. 16 front-end channels are embedded in the ASIC, with output logical-ORed on LVDS output to interface external TDC. Each channel includes a front-end buffer and a discriminator, both in current mode for higher bandwidth while reducing power. To compensate for inconsistency of propagation delay due to detector array layout and process variation, a programmable delay line is introduced for each channel. The delay line consists of coarse and fine delay cells with 165 ps and 33 ps resolution respectively and a dynamic range of 3000 ps. When connected to 16 2s2p SiPM (Hamamatsu S13360-3050PE) arrays with a total area of 5.76 cm², the system achieved a timing jitter of <500 ps FWHM.

Abstract

We present a CMOS-based QUBO solver ASIC architecture and its application to charged particle track reconstruction for high-energy physics. The solver implements a fully parallel spin-update engine operating on the Ising Hamiltonian Y = −(SUMij si Jij sj − Hi si) with 8-bit fixed-point coupling interaction coefficients, which gets mapped to Quadratic Unconstrained Binary Optimization(QUBO) problems via the standard spin-to-binary substitution xi = (si + 1)/2. The QUBO encodes track-finding physics through diagonal terms (geometric edge quality) and off-diagonal terms (triplet collinearity rewards and bifurcation penalties) derived from the Denby-Peterson formulation. The solver is evaluated as a front-end edge discriminator in a two-stage track reconstruction pipeline on TrackML simulated data. Unlike prior quantum annealing-inspired approaches that rely on a Gaussian KDE trained on ground-truth edge features, our method requires no supervised training or labeled-edge fitting — edge quality is determined entirely by the solver's combinatorial optimization over local neighborhoods. The pipeline achieves F1 = 84.1% (precision 89.3%, recall 79.6%), within 4% of the KDE-dependent baseline while exceeding it in precision.

Abstract

BaF_2 emits a prompt fast component with a sub-nanosecond decay time (~0.6 ns), ideal for ultrafast timing applications. Previous studies proved discriminated fast-component-dominant events based on pulse amplitude and slew rate characteristics could improve coincidence time resolution (CTR) in BaF_2. In this work, the fast-component discrimination method was implemented using FPGA-based dual-threshold time-over-threshold (DTOT) readout circuit, providing scalable architecture for multi-channel systems.

To reproduce the pulse amplitude and slew-rate characteristics used in previous full-waveform analysis using oscilloscope, the proposed DTOT method extracted amplitude-related, slew-rate-related parameters using two voltage thresholds applied to the pulse. Low-threshold TOT width provided amplitude-correlated parameter, while the timing difference between low- and high-threshold crossings provided pulse slew rate. Because fast-component-dominant events exhibited steeper rising edges, these parameters enabled fast-component discrimination without full waveform sampling.

The FPGA-based DTOT readout circuit consisted of BaF_2 coupled to VUV-MPPC SiPM, two-stage high frequency amplifier designed to provide sufficient gain with preserving rising-edge profile of fast component, low-latency comparators for accurate slew-rate extraction, and FPGA-based TDC for timestamping threshold crossings.In previous full-waveform analysis, CTR improved from 115 ps to 98 ps (14.8%) using the fast-component-dominant events. With the FPGA-based DTOT readout circuit, CTR improved from 126 ps to 109 ps (13.2%) using the fast-component-dominant events. These results demonstrated that FPGA-based DTOT readout circuit could identify the fast-component events and achieved considerable CTR improvement without full waveform sampling, providing a scalable and practically implementable method for ultrafast timing applications.

A Flexible Multi-Mode Digital Readout Architecture for High-Precision Low-Rate Time-of-Flight Detectors (#2425)

Manuel Viqueira Rodriguez[1], Joan Mauricio Ferré[2], Albert Espinya Rojas[2], José María Fernández-Tenllado[2], Miquel Ribalda Galvez[2], Rafel Manera Escalero[2], Juan José Silva García[2], Sara Portero Castillo[2], Gianmario Bergamin[1], Rafael Ballabriga[1], David Gascón[2], On behalf of PetVision project

[1] CERN, EP-ESE-ME, Meyrin, Switzerland; [2] Universitat de Barcelona, Institut de Ciències del Cosmos de la Universitat de Barcelona (ICCUB), Barcelona, Spain

Abstract

As chip design costs and complexity rises, the industry is increasingly shifting toward application versatility. The digital readout of the PoETIC chip, designed for custom Silicon Photomultiplier (SiPM) detectors within the PetVision project, embodies this philosophy, supporting Positron Emission Tomography (PET), mass spectrometry, and other high- precision low-rate (≤1 MHz) Time-of-Flight (ToF) applications. The architecture has 16 channels, with three thresholds each: (1) ≤1 photon Low Threshold (ThL), (2) a few-photons High Threshold (ThH), and (3) above ten photons Trigger Threshold (ThT). ThL and ThH are connected to dedicated Time-to-Digital Converters (TDCs), while the ThT signals are ORed into two groups of eight channels, connected to a separate TDC channel. Each TDC channel provides a ToF of 24.4ps time-bin and a Time-over-Threshold (ToT) of 390ps. Each channel integrates a track-and-hold circuit connected to an ADC for linear energy measurements. To optimize data transmission across diverse applications, the readout supports multiple operational modes and configurations. In low-bandwidth setups, several PoETIC chips can be daisy-chained to share a single communication link, reducing the required system resources. For data compression, a trigger operation mode reduces the data volume by transmitting a full bit-width reference ToF timestamp grouped with delta- encoded timestamps of other hits. For systems requiring external validation, the TDC digitizes the trigger validation signal generated by an external coincidence system so that only validated trigger events are transmitted. A data-driven operation mode allows the transmission of all hits in independent packets. The chip also offers control over ToF, non-linear energy measurement (ToT), and linear energy measurement data, allowing users to configure which information is sent, bit widths, and filtering to balance precision and bandwidth according to the specific requirements of the target application.

Analog Neural Network ASIC for In-Detector Processing: Experimental Validation of an Advanced Prototype (#2723)

Michele Ronchi[1,2], Mattia Amadori[1,2], Marco Carminati[1,2], Giacomo Borghi[1,2], Carlo E. Fiorini[1,2]

[1] Politecnico di Milano, Department of Electronics, Information and Bioengineering (DEIB), Milano, Italy; [2] Istituto Nazionale di Fisica Nucleare (INFN), Sezione Milano, Milano, Italy

This work is supported by Politecnico di Milano and by the Italian National Institute for Nuclear Physics (INFN), under project Analog Neural Network ASIC (ANNA) under Grant CSN5.

Abstract

Analog neural networks (ANN) are promising solutions for achieving fast and efficient data processing, usually trading-off accuracy for ultra-low power operation. For instance, in scintillator-based PET and SPECT gamma cameras, analog processing embedded in the analog acquisition chain can simplify the system design, reducing throughput, power consumption and scanner cost. After a first proof-of-concept, last year we proposed the design of a more advanced version of an Analog Neural Network ASIC (ANNA). We now present the preliminary experimental results of this ANNAv2 chip, fabricated in 110 nm CMOS technology. It features a fully analog charge-domain processing architecture enabling the implementation of configurable feedforward fully connected ANN. Each neuron consists of an efficient inverter-based charge integrator. Thanks to this programmability, its employment is not limited to emission tomography, but can be tailored to other scenarios in processing signals of "intelligent" detectors. The maximum supported complexity is 70 analog inputs with 5 weighted layers, up to 32 neurons per layer, and 32 analog outputs. Weights are quantized over 63 analog levels, with programmable non-linear activation functions. Preliminary measurements performed on the ASIC validate the correct operation of the proposed architecture and demonstrate the feasibility of fully analog end-to-end inference (with an energy cost of 2nJ/inference) for sensor front-end applications.

Abstract

Embedded FPGAs (eFPGAs) combine the performance and efficiency of custom silicon with the flexibility of programmable logic as reconfigurable digital logic can directly be integrated into ASICs. When designed with radiation tolerance techniques such as Triple Modular Redundancy (TMR), eFPGAs can support fault-tolerant and intelligent front-end processing. This enables systems to adapt to evolving data handling needs and environmental conditions, while also supporting local data reduction to lower cabling, power and backend processing demands. Building on previous prototype developments in 130nm and 28nm at SLAC, this paper details the ASIC development of a radiation-hardened eFPGA in 28nm CMOS using radiation-mitigation techniques to realize a reconfigurable logic fabric capable of reliable operation under fault-inducing conditions.

GEM detectors for the CMS muon system (#1040)

Chiara Aimè, On behalf of CMS Collaboration

Istituto Nazionale di Fisica Nucleare, Sezione di Pavia, Pavia, Italy

Abstract

The High-Luminosity upgrade of the Large Hadron Collider (HL-LHC) will subject the Compact Muon Solenoid (CMS) experiment to unprecedented particle rates and radiation levels. To maintain high-efficiency muon triggering and reconstruction in this challenging environment, CMS is upgrading its forward muon system, including Gas Electron Multiplier (GEM) technology. This program introduces two key stations: GE1/1 and ME0.

The GE1/1 station, composed of triple-GEM detectors, was installed during Long Shutdown 2 to complement the existing Cathode Strip Chamber stations in the $1.6 < |\eta| < 2.15$ region. Operational since the start of Run 3, GE1/1 has significantly enhanced redundancy and Level-1 trigger performance. This presentation reviews the operational experience gained during Run 3, focusing on detector performance, electronics optimizations, and the continuous improvements implemented to ensure seamless system integration.

Looking further ahead, the ME0 station is designed for installation during Long Shutdown 3 to extend the muon system's coverage up to $|\eta| = 2.8$. To withstand the high-rate environment of the HL-LHC, ME0 incorporates advanced design optimizations and robust background rejection capabilities. We present the current status of the ME0 project, including results from the latest prototype studies, time resolution performance, and the progress of the ongoing mass production.

Together, these GEM upgrades are pivotal for extending the physics reach of CMS, ensuring high-quality muon identification and tracking in the most demanding regions of the detector.

NSS-24-02

A new detector technology for the LHCb Muon system in the high luminosity era (#2159)

Francesco Debernardis

INFN-Bari, Fisica, Bari, Italy

Abstract

A novel Micro-Pattern Gaseous Detector (MPGD) technology based on μ-RWELL is under development as a potential replacement for the most irradiated regions of the LHCb muon system at CERN, in view of the Upgrade II

program. The μRWELL is a resistive MPGD featuring a compact single-stage amplification structure with typical gains up to 10^4, making it well suited for operation in harsh radiation environments. An improved detector layout, the G-RWELL, is currently under study. This configuration enhances the standard μ-RWELL design by introducing a single GEM pre-amplification stage, allowing gains up to 10^5 under stable operating conditions. These features make the technology suitable for the extreme rate capability required at the future LHC high-luminosity conditions, where peak luminosity of L = 1.5×10^{34} $cm^{-2}sec^{-1}$ is planned. The presentation will focus on the ongoing research activities on these detector technologies in the context of the LHCb muon Upgrade II. Particular emphasis will be given to recent testbeam campaigns at the CERN PS beam line, involving the use of the FATIC front-end electronics, currently under development, and a dedicated data analysis framework optimized for this readout.

NSS-24-03

A Straw Tube Chamber Prototype for the Inner Detector of a Future e^+e^- Collider Experiment (#2774)

Oliver Kortner, Sandra Kortner, Hubert Kroha, Nick Meier, **Julia Okfen**, Robert Richter, Jörg Zimmermann

Max Planck Institute for Physics, ATLAS Research Group, Munich, Germany

Abstract

The Future Circular electron-positron Collider, proposed as future flagship at CERN, offers a unique opportunity for precision measurements of the Higgs boson and electroweak properties. To meet the stringent requirements of a future Inner Tracker in terms of momentum resolution, particle identification, and minimal material budget, a scalable, ultra-light gaseous detector concept based on straw tubes is under development.

This contribution presents the design and construction of a 1.5 m-long straw tube chamber prototype.

As part of the mechanical feasibility study, the importance of the tube wall pre-tensioning during assembly was identified to prevent a drift radius asymmetry.

Via a CERN test beam validation a comprehensive study of the prototype has been performed. The applied grounding scheme was successful, since the noise rates are below 100 Hz.

Through a muon detection efficiency of 100% except for a narrow region close to the tube wall and a spatial resolution of 118 μm, the suitability of the straw tube tracker for an inner detector of a future e^+e^- collider experiment is demonstrated.

Combining the test beam data with Garfield++ simulations allows for a prediction of the expected the particle identification capabilities, yielding a π/K separation mostly better than 3σ up to momenta of 10 GeV.

Owing to their reduced material budget, straw tubes exhibit a low gamma conversion probability, although the resulting Compton electrons are not stopped within the thin tube wall.

Subsequently, crucial input for the optimization of future prototypes is provided, which is directly addressed in the next generation 4 m-long straw tube chamber prototype.

This contribution will additionally present the latest performance results from the up-scaled 4m prototype, obtained during the upcoming CERN test beam campaign in July.

Abstract

This work presents performance measurements of the first neutron detector module developed for the Cold Neutron Spectrometer (CSPEC) hosted at the European Spallation Source (ESS). Designed and built at the Laue-Langevin Institute (ILL), the detector employs a two-dimensional Multitube architecture to meet the CSPEC requirements in terms of spatial resolution count rate capability and amplification gain stability and uniformity. Experimental tests completed at the CT2 detector test beamline of ILL, confirm compliance to these detection features while validating the production process for the next modules.

Characterization of a High-efficiency Multi Element Thick Gas Electron Multiplier Based Neutron Dosemeter (#1312)

Haoshuai Wang[1,2], Soo Hyun Byun[1,2]

[1] McMaster University, Department of Physics and Astronomy, Hamilton, Canada; [2] McMaster University, Radiation Sciences Graduate Program, Hamilton, Canada

The authors would like to thank the CANDU Owners Group (COG), Canada, and the Natural Sciences and Engineering Research Council (NSERC), Canada for financially supporting this work.

Abstract

We report characterization of a high-efficiency multi-element neutron dosemeter built by the Thick Gas Electron Multiplier (THGEM) technology. The multi-element configuration is an excellent way to increase neutron detection efficiency and is well suited for the development of tissue-equivalent proportional counters (TEPCs) for microdosimetric measurements in low-intensity neutron fields. Compared to conventional TEPCs, the THGEM-based design eliminates the need for anode wire structures, thereby simplifying fabrication and assembly processes. Moreover, the capability of cascading multiple THGEM layers to achieve higher gain, combined with its low cost, mechanical robustness, and large-area scalability, are advantageous features of the THGEM for building multi-element detectors. Following the successful development of an initial prototype consisting of twenty-one gaseous sensitive volumes, an upgraded detector with ninety-five sensitive volumes has been developed to increase neutron efficiency even higher. Experimental characterization of the new detector is currently underway using ^{238}PuBe and ^{7}Li(p,n) neutron sources at the McMaster Accelerator Laboratory. The signal performance and dosimetric response of the detector will be presented and compared with Monte Carlo simulation results.

Abstract

Conventional gaseous detectors rely on electron drift, but this transport is intrinsically limited by diffusion, particularly in noble-gas mixtures and over long drift distances. Electronegative additives offer an attractive alternative because they rapidly capture electrons and form negative ions, which drift with much smaller diffusion, enabling improved spatial resolution. In this work, Xe-SF_6 mixtures were investigated using a dedicated experimental setup to study electron attachment, ion mobility, electron detachment, charge multiplication, and electroluminescence. Near-total electron attachment was observed in all cases, confirming the efficient formation of negative ions in Xe-SF_6 mixtures. In the low-field regime, two negative-ion species, SF_6^- and clustered $SF_6^-(SF_6)$, were identified, with reduced mobilities remaining independent of the electric field. High electric fields inside GEM holes enabled electron detachment and subsequent amplification, with EL and multiplication thresholds shifting to lower fields and gas gains increasing as the SF_6 concentration decreased. Xenon electroluminescence was also observed in these mixtures, both inside the GEM and after, although strongly quenched by the electronegative additive. The increase in the thresholds for both scintillation and charge multiplication with increasing SF_6 fraction, highlight the central role of the detachment processes in the amplification mechanisms. These results demonstrate that even a very small addition of SF_6 can substantially modify xenon transport properties. However, the usual amplification stages are not immune to these changes.

This work was sponsored by the Office of Naval Research (ONR) as part of 6.1 funding.

Abstract

The objective of the Neutron Radiation Detection Instrument (NeRDI) series of experiments is to space qualify and characterize the long-term performance of these new detector technologies in on-orbit radiation environments. The second of this series of experiments, NeRDI-1B, launched on 21 April 2025 to the International Space Station as part of the Department of Defense Space Test Program-Houston 10 (STP-H10) mission. The NeRDI-1B instrument comprises two arrays of Domino microstructured semiconductor neutron detectors (MSNDs), a single separate MSND sensor, and an EJ-270 plastic scintillator read out by a custom array of silicon photomultipliers. Here we describe the NeRDI-1B instrument and present an analysis of its first year of on-orbit operations, with particular focus on the characterization of the MSNDs.

NSS-25-02

High-speed single-photoelectron detection for Cherenkov astronomy (#1412)

Luca Giangrande[1], Matthieu Heller[2], Teresa Montaruli[2]

[1] University of Geneva, Particle and nuclear physics, Geneva, Switzerland; [2] University of Geneva, Département de physique nucléaire et corpusculaire - DPNC, Geneva, Switzerland

Abstract

Silicon photomultipliers are increasingly replacing photomultiplier tubes in Cherenkov telescope cameras, but achieving single-photoelectron resolution with nanosecond timing in a low-noise, scalable detector system emains challenging. We present a co-designed SiPM sensor and front-end application specific integrated circuit (ASIC) that meets these requirements. The custom hexagonal sensor, developed with Hamamatsu Photonics, incorporates an integrated optical filter and fourfold pixel segmentation. The readout is performed by a second prototype of the FANSIC ASIC, optimized for this application and fabricated in 65 nm standard CMOS technology, provides eight channels with on-chip analog summing of sub-channels on a 3.5×3.5 mm2 die, while consuming only 24 mW per

channel. We demonstrate clear single-photoelectron peak separation
with a gain of 2.7 × 10−12 V · s , and an impulse response below 4 ns full width at half maximum with a 1.7 ns rise time, preserving the nanosecond-scale structure of Cherenkov pulses. The system esponds linearly from 1 to 130 photoelectrons, and 55 distinct photoelectron peaks are resolved by varying the source intensity.These results demonstrate that the integrated sensorelectronics architecture delivers the speed, resolution, and dynamic range required for imaging atmospheric Cherenkov telescopes, and provides a scalable path toward large-area camera modules.

Abstract
This paper reports on the effects of thermal neutrons in a plastic-scintillator-based sampling calorimeter for a rare kaon decay experiment and the results of experimental studies demonstrating their suppression. We prepared a prototype detector consisting of a lead/scintillator sampling calorimeter with a transverse size of 25 × 25 cm² and 25 alternate layers of 1-mm-lead and 5-mm-scintillator. The prototype can accommodate 50 boron carbide sheets (0.1 mm thick), detachably mounted between the lead and scintillator layers to absorb thermal neutrons. We irradiated the prototype detector with a 0.9 GeV/c π^- beam at J-PARC and demonstrated the existence of late signals which are thought to be γ-rays from capture of thermal neutrons induced by the interaction of charged pions. Furthermore, we separately confirmed, by utilizing a radioactive neutron source, that the insertion of boron carbide sheets reduces the detection of thermal neutrons. These results demonstrate that boron loading is effective in suppressing accidental signals originating from pion-induced thermal neutrons.

Abstract

Radioactive Ion Beams (RIBs) are the frontier in Nuclear Physics, allowing investigations of low cross-section reactions and of nuclei far from the stability valley. Silicon carbide (SiC) material can overperform Silicon as a charged-particle detector, offering nearly zero leakage current and visible-light blindness thanks to the high bandgap. The high displacement energy of SiC is synonymous of radiation hardness and the saturation velocity higher than Si makes SiC an excellent material for fast, high-rate radiation detectors in nuclear and medical physics. In order to provide effectively RIBs tagging, even in the case of high intensity beams, like the ones foreseen at the Laboratori Nazionali del Sud of INFN in Catania (Italy), produced by the novel high intensity Radioactive Ion Beams (RIBs) facility named FRAISE, novel detection systems for the diagnostics and the tagging of RIBs along the transport line and in the measurement chamber are requested. To this aim and for the need of other particle accelerators around the world, we are developing a novel high performance, mid-format detection system, based on an array of Silicon Carbide (SiC) diodes, readout by an optimized fast frontend electronics. This contribution deals with the design, the study and the experimental qualification of the performance of the proposed mid-format detection system with particular care in the characterization of the timing properties and in the analysis of the limiting factors affecting the time resolution. For deposited energies above 2 MeV the time resolution keeps below 100 ps rms at zero added input capacitance. At 22pF added capacitance, the measured time resolution is below 100 ps rms above 5 MeV injected energy.

NSS-25-05

The General Antiparticle Spectrometer (GAPS) Instrument: Design, Performance, and First Antarctic Flight (#2247)

Kelsey Yee, On behalf of the GAPS collaboration

Massachusetts Institute of Technology, Cambridge, USA

GAPS is a collaboration of over 60 scientists and engineers. The work presented here is possible thanks to all of their contributions. The GAPS Experiment is funded in the U.S. by the NASA APRA program grants NNX17AB44G, NNX17AB46G, NNX17AB47G, and 80NSSC21K187, in Japan by the JAXA/ISAS Small Science Program FY2017, and in Italy by Istituto Nazionale di Fisica Nucleare (INFN) and the Italian Space Agency (ASI) through the ASI INFN agreement No. 2018-22-HH.0. The Columbia University GAPS group is supported by the Heising-Simons Foundation award 2025-6055. K. Yee is supported through the NSF Graduate Research Fellowship under grant 2141064.

Abstract

The General Antiparticle Spectrometer (GAPS) is an Antarctic balloon experiment designed to search for low-energy cosmic antiparticles as signatures of dark matter. The GAPS instrument flew on an Antarctic long-duration balloon platform for 25 days in the 2025 austral summer, proving several novel technologies for the first time in flight. The detection method employed by GAPS involves a low-energy antiparticle slowing to a stop within the tracker, forming an exotic atom; the subsequent decay releases characteristic X-rays and nuclear annihilation products that are detectable by the instrument. GAPS utilizes a plastic scintillator time-of-flight (TOF) system that measures energy depositions and velocities and provides a system trigger, together with a tracker consisting of over 1000 lithium-drifted silicon (Si(Li)) strip detectors that provides energy and position measurements, as well as X-ray detections. The tracker operating temperature of < -35 °C is achieved with a novel multi-loop capillary heat pipe (MCHP) thermal system that passively transfers heat generated in the tracker to a large-area radiator. This contribution details the instrument design, performance from ground commissioning, and first Antarctic flight of the GAPS instrument.

Abstract

HYPATIA is a next-generation scintillator detector array under development for in-beam gamma-ray spectroscopy of exotic nuclei at the Rare Isotope Beam Factory (RIBF), at the RIKEN Nishina Center for Accelerator-Based Science. When completed, the array will consist of 1008 advanced scintillator detector crystals (384 HR-GAGG and 624 $CeBr_3$), in a hybrid configuration to deliver improved energy resolution, fast timing, enhanced background suppression and peak-to-total. This work presents the development and characterisation of $CeBr_3$ detector modules produced at the University of York for integration into the HYPATIA array. Each module consists of four $CeBr_3$ crystals coupled to silicon photomultiplier arrays within a compact, hermetically sealed housing, designed to ensure the long-term performance stability of the hygroscopic scintillators, whilst optimising the detection efficiency. Experimental characterisation demonstrates an energy resolution of 4.1% – 4.3% at 662 keV and a timing resolution of approximately 0.6 ns (FWHM) for the coincident ^{60}Co gamma rays. These results validate the module design and confirm its suitability for the high-precision spectroscopic measurements required to explore the limits of nuclear stability.

Emergent Physical Interpretability in Transformer Encoders for Radiation Anomaly Detection (#1513)

Derian M. Mowen, Miltiadis Alamaniotis

University of Texas at San Antonio, Electrical Engineering, San Antonio, USA

This material is based upon work supported by the Department of Energy National Nuclear Security Administration through Defense Nuclear Nonproliferation's Enabling Capabilities in Technology Consortium under Award Number DE-NA0004197.

Abstract

Constraining a Transformer decoder to a known physical generative structure induces emergent interpretability in the encoder's self-attention without labels or supervision. We demonstrate this in gamma-ray spectroscopy, where measurements are Poisson-sparse at one-second mobile survey dwell times, environments are nonstationary, and labeled decompositions are unavailable. Observed spectra arise as nonnegative additive superpositions of source contributions, which we encode using a Nonnegative Matrix Factorization (NMF)-constrained decoder paired with a Transformer encoder. The learned representations organize into physically meaningful components, separating environmental substructures and recovering known photopeak features at correct energies. In contrast, an identical Transformer with an unconstrained decoder produces unstructured latent representations, with 48.6% of weights taking negative values that are inconsistent with photon-counting physics, isolating the decoder constraint as the causal mechanism. The proposed architecture achieves state-of-the-art anomaly detection on 6,221 field-collected spectra, outperforming linear baselines and unconstrained autoencoders while exhibiting reduced run-to-run variance, demonstrating that embedding known generative structure into decoder design can induce interpretable representations across domains governed by additive physical processes.

This research was funded by the 'New Faculty Research Support Grant' at Changwon National University in 2025.

Abstract

Reconstruction of surface radiation contamination from sparse airborne measurements has matured rapidly with deep learning, but a validation gap persists: the surface activity is rarely measurable in operational deployments, leaving no oracle for evaluating predictions. We address this by reframing airborne mapping as an inverse deconvolution problem in which a known forward operator maps surface activity to aerial fluence via altitude blur and detector response. The framing yields a ground-truth-free validation protocol: each candidate surface reconstruction is forward-simulated through the operator and compared to held-out aerial measurements. We characterize the protocol on a synthetic benchmark with a 64-by-64 ground-truth surface of Gaussian hotspots, a fixed Gaussian forward kernel, 150 sparse aerial samples per scene, and 200 held-out validation points. Four reconstructions are compared: inverse distance weighting (IDW), ordinary kriging, IDW followed by Wiener deconvolution, and a small encoder-decoder convolutional network. Across 40 scenes per method, the round-trip aerial-space root-mean-square error correlated with the oracle surface-space root-mean-square error, with a pooled Pearson correlation of 0.871 across methods and within-method correlations from 0.71 to 0.82. The protocol identified the encoder-decoder network as the most accurate reconstruction in agreement with the oracle ranking, without access to ground truth. These findings suggest that round-trip forward-simulation residuals can serve as a practical proxy for surface reconstruction quality, supporting evaluation and benchmarking of radiation mapping methods when direct surface ground truth is limited or unavailable.

Backscattered Spectral Network Imaging Method Based on a Combined Long–ShortCrystal Detector (#2600)

Junjun Li[1,3], Yongshun Xiao[1,3]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Tsinghua University, Department of Engineering Physics, Beijing, China; [3] Key Laboratory of Particle & Radiation Imaging (Tsinghua University), Ministry of Education, Beijing, Beijing, China; [4] Key Laboratory of Particle & Radiation Imaging (Tsinghua University), Ministry of Education, Beijing, Beijing, China

Abstract

Compton backscatter imaging (CBST) is a promising non-contact technique for nondestructive testing of complex structures, but its performance is limited by the trade-off between detection efficiency and spatial resolution. In this work, we propose a backscattered spectral network imaging framework based on a combined long–short crystal (CLSC) detector and a spectral fusion neural network. The CLSC detector integrates alternating long and short scintillation crystals to improve photon detection efficiency while retaining geometric selectivity, and segmented metal collimation is introduced to provide depth-dependent scattering information. The acquired multi-crystal spectra are processed by a dual-branch fusion network that jointly exploits spectral and spatial features for defect reconstruction. Geant4 simulations with varying defect sizes and depths under realistic noise conditions demonstrate that the proposed method outperforms conventional count-based and collimator-free approaches under low-count conditions, enabling more reliable detection of deep and small defects.

A Machine Learning Approach to Inter-Crystal Scattering Kinematics for Multiple Emission Tomography (#2796)

Lisa Arnone[1], Matteo N. Colombo[1], Giulia Terragni[2], Francesco Pennazio[3], Marco Paganoni[1], Luca Presotto[1], Etiennette Auffray[2], Marco Pizzichemi[1,2]

[1] University of Milano-Bicocca, Milan, Italy; [2] CERN, Geneva, Switzerland; [3] INFN Torino, Turin, Italy

This work is supported by the European Union-Next Generation EU, Mission 4 Component 1 CUP H53D23007430001 “Multiple Emission Tomography”, and carried out in association with the CERN Crystal Clear Collaboration.

Abstract

High spatial resolution and sensitivity in Positron Emission Tomography (PET) are essential for early diagnosis and treatment monitoring. However, in modern pixelated detectors, a large fraction of coincidence events involves Inter-Crystal Scatter (ICS), where a gamma ray deposits its energy across multiple scintillators through a Compton interaction followed by photoelectric absorption.These events are difficult to exploit because the sequence of interactions cannot be directly determined, degrading the reconstruction of the Line of Response and, consequently, the spatial resolution. For this reason, ICS events are often discarded, leading to a significant loss in sensitivity. The Multiple Emission Tomography (MET) project aims to recover these events and use them to enable

a hybrid imaging approach combining PET and Compton camera capabilities. In conventional approaches, ICS reconstruction relies on analytical methods based on chi-squared minimization and manually tuned selection cuts. Although effective, these methods are computationally intensive and strongly dependent on user-defined criteria, limiting both efficiency and scalability. In this work, we introduce a Machine Learning (ML) pipeline integrated into the MET prototype to automatically identify ICS events and determine their interaction sequence. By replacing the analytical reconstruction with XGBoost classifiers and a Convolutional Neural Network, the proposed approach provides a more flexible and efficient solution, improving the identification of the first interaction point and enabling a more effective use of multi-crystal events.

Real-Time Data Compression Using Machine Learning for the ARGO Dark Matter Detector (#1376)

Sajedeh Esmaeilzadeh[1], Charles-Etienne Granger[1], Hamza Ezzaoui Rahali[1], Kevin Gracequist[2], Simon Viel[2], Audrey C. Therrien[1]

[1] Sherbrooke universuity, Interdisciplinary Institute for Technological Innovation(3IT), Sherbrooke, Canada; [2] Carleton University, Department of Physics, Ottawa, Canada

This research was undertaken, in part, thanks to funding from Canada Foundation for Innovation, CMC Microsystems, NSERC discovery grant program and Canada Research Chairs Program. Audrey C. Therrien holds the Canada Research Chair in Real-Time Intelligence Embedded for High-Speed Sensors.

Abstract

Abstract—The search for dark matter requires increasingly advanced detectors and data processing systems. The ARGO detector, under development, uses liquid argon as the detection medium and will deploy Single Photon Avalanche Diodes (SPAD) over approximately 200 m2. These SPAD matrices, arranged in mm2 units, will generate millions of data channels, with potential drawbacks such as high power consumption, complex cabling, and costly high-speed data storage. To address these challenges, we investigate a unified real-time machine learning (ML) approach capable of simultaneously performing particle identification and event position reconstruction. The proposed Convolutional Neural Network (CNN) architecture classifies events as nuclear recoils (NR), electron recoils (ER), or alpha decays, while concurrently reconstructing the interaction position inside the detector. This multi-task approach reduces computational resources, making it well suited for resource- constrained edge environments near the detector. Future work will focus on optimizing the models and implementing them on edge hardware.

Machine-Learning Based Rapid Characterization of HPGe Detectors Based on Full-Energy Peak Efficiency Responses (#1052)

Kainan Zhang[1,2], Pengwen Su[1,2], Zhen Wu[1,3], Ankang Hu[1,2], Hui Zhang[1,2], Junli Li[1,2], Rui Qiu[1,2]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Key Laboratory of Particle & Radiation Imaging, Tsinghua University, Ministry of Education, Beijing, China; [3] Nuctech Company Limited, Beijing, China

Abstract

Full-energy peak efficiency (FEPE) is a critical quantity for quantitative gamma-ray spectrometry using HPGe detectors. However, the FEPE response may vary during long-term operation because of operational history and environmental conditions. Conventional detector characterization usually requires repeated Monte Carlo simulations, in which selected geometrical parameters are manually adjusted until the simulated FEPE curve agrees with experimental measurements. This iterative procedure is computationally expensive and strongly dependent on operator expertise.

To address this limitation, this work proposes a machine-learning-based rapid characterization framework using a sparsely connected multilayer perceptron (MLP) with multiple attention heads. By taking experimentally determined FEPE values and fixed detector parameters as inputs, the network directly determines key characterization parameters, including the crystal radius, crystal length, and dead layer thickness.On a test set comprising 13 detector instances with different specifications, the proposed framework performed detector characterization, and the simulated FEPEs of the characterized detectors agreed closely with the corresponding experimental FEPEs, demonstrating the broad applicability of the approach. Owing to the feed-forward nature of the MLP architecture, the characterization procedure can be completed rapidly through a single forward pass, providing an efficient alternative to the conventional manual Monte Carlo adjustment workflow.

Comprehensive Strategy for Track Signal Extraction in the COMET Phase-I Experiment using Deep Learning Algorithms (#2397)

Joe Sato

Yokohama National University, Deapartment of Physics, Yokohama, Japan

This work was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI Grant Numbers JP18H05231, JP18H05543, and 25H01524.

Abstract

The COMET Phase-I experiment searches for the neutrinoless muon-to-electron conversion with a target sensitivity of 7×10^{-15}. A critical challenge is identifying signal hits amid a high background occupancy of approximately 40\% in the Cylindrical Drift Chamber (CDC). Traditional methods struggle under such dense environments. We present a deep-learning-based hit filtering strategy using a U-Net architecture with an EfficientNet backbone. By optimizing image formats and multi-hit handling, we achieved a purity of 98\% and a retention of 90\%, significantly surpassing design goals. This framework establishes a robust foundation for track reconstruction in high-occupancy environments.

Signal Electron Extraction and Energy Resolution the COMET Experiment (#1795)

Yuya Kojima

Yokohama National University, Graduate School of Engineering Science, yokohama, Japan

Abstract

Charged lepton flavor violation (CLFV) is a promising probe of physics beyond the Standard Model. The COMET Phase-I experiment searches for coherent muon-to-electron conversion ($\mu^- \text{–} e^-$ conversion), which produces a mono-energetic electron with an energy close to 105 MeV. However, Decay-In-Orbit (DIO) electrons form a major background near the signal region, requiring precise track reconstruction and energy estimation.

In this study, a U-Net–based deep-learning method was applied to Cylindrical Drift Chamber (CDC) hit information represented as two-dimensional images. Hit wires with deep-learning scores above a threshold were treated as signal hits and passed to GenFit for track reconstruction. Quality cuts based on the p-value, the number of degrees of freedom (NDF), and reduced χ^2 were also applied to improve the reconstruction quality.
The ROC curve evaluation demonstrated effective discrimination between signal-electron hits and background hits. Furthermore, applying the selected hits to GenFit improved the momentum residual distributions compared with the conventional reconstruction method. In particular, the combination of hit selection and quality cuts suppressed events with large momentum residuals contributing to the DIO background and reduced the overlap between the DIO background and the signal region. Smearing evaluations using the obtained momentum residual distributions and the theoretical DIO spectrum indicated improved energy reconstruction performance under the condition corresponding to a conversion rate of CR = 3.0×10^{-15}. These results suggest that deep-learning-based hit selection can improve track reconstruction and energy estimation performance in the COMET experiment.

Abstract

Conventional measurements of neutron-induced charged-particle emission cross sections with semiconductor detectors are limited by particle energy loss in samples and stringent experimental constraints.The $^{14}N(n, p)$ reaction is critical for dose evaluation in boron neutron capture therapy, as it dominates radiation dose to healthy tissue under thermal and epi-thermal neutron irradiation. High-precision cross-section data with uncertainties below 5% are indispensable for safe treatment planning, while existing datasets are currently under re-evaluation. This work aims to accurately measure the $^{14}N(n, p)$ reaction cross section from 2.6×10^{-3} to 1.8 eV using a homemade sample-added scintillator detector. The scintillator consists of a base matrix, ^{14}N-containing luminescent agent, wavelength shifter and photoinitiator. Pure scintillators and sample-added scintillator with lithium fluoride and gold powder are fabricated as active targets, attached directly on the surface of a photomultiplier tube, and aligned on the neutron beam. Experiments are carried out at the ANNRI beamline of the MLF of the JPARC with a flight length of 28.41 m. Waveform signals were recorded by a digitizer, with long-gate pulse height area, short-gate pulse shape discrimination area and time-of-flight data acquired for each event. The $^{14}N(n, p)$ cross section was determined relative to the $^{6}Li(n, \alpha)$ reaction. Results indicates that the cross sections obtained in the present work show an overall energy dependence consistent with the expected low-energy 1/v behavior, and the measured values are consistent within uncertainty with the past experimental values and evaluated cross section data. This study demonstrates the feasibility of using self-made sample-added scintillators for measurements.

Abstract

Thermal-neutron detection in intense gamma-ray fields is required for fuel-debris monitoring and criticality safety during nuclear decommissioning. We developed co-doped Ce:$LaBr_3$/^{6}LiBr eutectic scintillators in which the ^{6}LiBr phase converts thermal neutrons through the ^{6}Li(n,α)^{3}H reaction and the Ce:$LaBr_3$ phase produces fast scintillation light. Building on eutectic-scintillator design concepts that enable higher Li content than stoichiometric single crystals, Sr^{2+} and Ba^{2+} co-doping were investigated to improve pulse-shape discrimination (PSD). Sr co-doping produced only limited improvement in the eutectic because Sr-rich secondary regions were formed, whereas Ba co-doping gave clearer α/γ PSD mapping. A Ce:$LaBr_3$/^{6}LiBr detector was then evaluated in the same ^{252}Cf-neutron/^{137}Cs-gamma mixed-field configuration and digital processing scheme as the optimized LiCAF:Ce detector benchmark. Neutron-source detection was demonstrated up to 5.4 Gy/h with an effective thermal-neutron sensitivity of approximately 0.3 cps/nv, indicating the potential of Ba,Ce:$LaBr_3$/^{6}LiBr eutectics for compact neutron monitoring in decommissioning environments.

NSS-27-03

Scintillators based on 2D perovskite single-crystals for the detection of rapid neutrons and gamma/neutron discrimination. (#1344)

Fanny Thorimbert[1], Eric Gros-Daillon[2], David Tisseur[3], Olivier Llido[3], Victor Buridon[5], Dominique Tromson[5], Jean-Marie Verilhac[1]

Abstract

Fast neutron detectors are essential for quantifying neutron flux in nuclear reactors, imaging the internal structure of large equipment, and detecting contraband or radioactive nuclear materials. However, no ideal technology currently enables efficient, accurate, and real-time detection of fast neutrons, which are high-energy, highly penetrating particles. There is a growing interest in hybrid organic–inorganic halide perovskites, which exhibit scintillation under X-rays, gamma rays, and fast neutrons within a single material platform. In particular, two-dimensional (2D) perovskites contain both light elements, such as hydrogen in long organic cations, which are suitable for neutron detection, and heavy elements, such as lead, which enhance X- and gamma-ray absorption [1,2].

In this presentation, I will present our approach to grow from solution by solvent evaporation, centimeter-sized single crystals of 2D perovskites, namely PEA_2PbBr_4. The optical characterizations of this single-phase, perfectly ordered crystal present two photoluminescence (PL) peaks, at 411 and 426 nm, attributed respectively to the emission from the surface and the bulk, a PLQY (Photoluminescence Quantum Yield) of 26 %, and a time decay of ≈ 3 ns. The radioluminescent measurements show a result of 20000 to 30000 Ph/MeV vs LYSO, which is better than organic scintillators, like EJ200~10000 Ph/MeV. In a second step, we will dope the reference material with cations such as Zn^{2+} or Mn^{2+} to enhance the light yield and increase the Stokes shift in order to reduce the self-absorption. We will also investigate the effects of dimensionality and halide composition to achieve a PL redshift. All synthesized materials will be evaluated under realistic neutron flux conditions, with particular attention to their stability. In parallel, their ability to discriminate between neutron and gamma radiation will also be investigated on a laboratory bench, using a ^{252}Cf source.

Abstract

$Cs_2LiLa(Br,Cl)_6$:Ce (CLLBC) is a promising Elpasolite scintillator for compact gamma-ray spectroscopy and thermal-neutron detection, but the effect of Ce concentration on neutron-gamma pulse-shape discrimination (PSD) remains insufficiently quantified. In this work, CLLBC crystals with 20% Cl substitution and nominal Ce concentrations of 2%, 3%, and 4% were grown by the vertical Bridgman method. When Ce concentration increasing from 2.05% to 5.46%, the 662 keV energy resolution improved from about 3.5% to 3.2%, the relative light output increased by 9.4%, and the neutron-gamma figure of merit (FOM) increased from 1.6 to 2.0. Scintillation-decay measurements and coupled rate-transport calculations indicate that higher Ce concentration enhances energy transfer and excitation-density-dependent quenching, making neutron-like pulses more distinct from gamma-ray pulses. Continued growth optimization further enabled a 1 inch SiPM-coupled CLLBC detector that achieved 3.19% energy resolution at 662 keV and FOM = 2.37. These results demonstrate a practical route for improving CLLBC scintillators for compact mixed-field radiation detectors.

Abstract

Tl- and ^{6}Li-co-doped $Cs_3Cu_2I_5$ crystals were grown by the Bridgman method and evaluated as thermal neutron scintillators for application in fiber-optic-coupled neutron flux monitoring systems. The grown crystals (5 × 5 × 3 mm) exhibited a light yield of approximately 140,000 ph./n_{th}excited thermal neutron, which is approximately 24 times higher than that of the conventional and widely used GS20 neutron scintillator. A detector was constructed by optically coupling a small crystal piece (1 × 1 × 0.2 mm) to the tip of a 20 m optical fiber. Neutron irradiation experiments were conducted at the Kyoto University Research Reactor. The neutron excited radioluminescence spectra of Tl,^{6}Li doped $Cs_3Cu_2I_5$ were confirmed. In addition, the scintillation intensity varied linearly with neutron flux, with a coefficient of determination of R^2 = 0.996. These results indicate that ^{6}Li- and Tl-co-doped $Cs_3Cu_2I_5$ is a highly promising scintillator material for real-time neutron dosimetry in high-flux environments such as boron neutron capture therapy.

Abstract

Traditionally dual-mode radiation detection requires a combination of two or more radiation detectors that work synchronously. In recent years more novel and advanced scintillation detector materials for dual-mode detection

have been discovered and developed. Recent elpasolite scintillators, such as cerium doped CLYC, CLLB, and TLYC, which contain neutron sensitive materials, have been investigated as dual mode detectors. Because of the complexity of their phase diagrams, crystal growth yield, including bulk uniformity and detection performance, is lower than ideal, which eventually leads to a high final product cost. As a result, there is not a widespread interest in using these scintillators due to their high costs and scarcity although they have good detection and gamma-neutron performance. Simpler compounds like binary and ternary halides have less complicated phase diagrams due to fewer reacting compounds in the growth systems. This paper describes the efforts to grow scintillators that are capable of simultaneous neutron and gamma ray detection with lithium-doped or containing ternary halide compounds. The presence of lithium, whether it be natural or enriched ^{6}Li, improves the neutron sensitivity of the compounds and allows for simultaneous detection of gamma-ray and thermal neutrons. Fast or scattered neutron detection is also possible with ternary chloride compounds. This paper presents the growth and characterization of lithium based ternary halide scintillation crystals for dual-mode neutron-gamma detection and imaging. Early results show an energy resolution about 4% (FWHM) for 662 keV gamma-rays and a primary decay constant about 800 ns. Other properties, such as melting points, transmittance and absorbance spectra, x-ray excitation optical emission spectra, as well as preliminary neutron gamma discrimination and crystal structure measurements will be presented.

Neutron and Gamma Ray Pulse Shape Discrimination in Small, Fiber-Coupled Organic Glass Scintillators (#1730)

Schuyler Tyler, Oscar Stennes, Shaun D. Clarke, Sara A. Pozzi

The University of Michigan, Department of Nuclear Engineering and Radiological Sciences, Ann Arbor, USA

This work was supported in-part by the Consortium for Monitoring, Technology, and Verification under Department of Energy National Nuclear Security Administration award number DE-NA0003920. The authors thank collaborators at École Polytechnique Fédérale de Lausanne (EPFL) for their technical discussions, continued support, and contribution of detector materials used in this work.

Abstract
Miniature fiber-coupled organic scintillators are promising candidates for distributed neutron measurements in confined or high-radiation environments where remote placement of photodetectors and electronics is desirable. In this work, organic glass scintillator (OGS) droplets coupled to polymethyl methacrylate (PMMA) optical fibers were

characterized to investigate how optical transport distance affects pulse-shape discrimination (PSD) behavior and neutron-sensitive response. Measurements were performed using direct coupling and fiber lengths up to 12 m with ^{252}Cf and ^{137}Cs sources. Tail-to-total PSD was used to compare neutron and gamma-ray event populations under fixed photomultiplier operating conditions. Increasing fiber length produced substantial attenuation and broadening of both pulse populations, with the gamma-ray band degrading more rapidly than the neutron band. Low-light transport effects, coupling conditions, and threshold migration also significantly altered the PSD morphology as fiber length increased. Although low-energy calibration features were difficult to interpret due to the small scintillator geometry and probable electron escape effects, measurable neutron-sensitive PSD structure remained observable across all tested fiber lengths. These results suggest that long PMMA optical transport may preferentially suppress gamma-ray response while preserving neutron-sensitive discrimination capability relevant to neutron-signature analysis and remote neutron monitoring applications.

Abstract
Scintillators, which convert ionizing radiation into visible photons, are essential in applications ranging from high-energy physics to medical imaging. Plastic scintillators are especially attractive due to their low cost, fast response, and simple fabrication. However, their limited radiation hardness and poor geometrical adaptability restrict their use

in demanding environments such as hadron therapy and real-time dosimetry. In this work, a novel nanocomposite scintillator designed for 3D printing is investigated. The material consists of a photocurable polysiloxane matrix embedding metal-halide perovskite (CsPbBr3) nanocrystals, enabling the fabrication of complex detector geometries. Beyond its manufacturability, the composite exhibits an unusual scintillation response: under alpha-particle excitation, the emitted signal shows a significantly longer decay time compared with the fast emission typical of pure perovskites. These temporal features allow effective pulse shape discrimination between gamma photons and alpha particles, representing, to the best of the authors' knowledge, the first demonstration of this capability in hybrid perovskite-based scintillators. Preliminary optical characterization was carried out through spectrofluorimetric analysis to study the interaction between the polymer matrix and the perovskite phase, while UV--visible transmittance measurements confirmed adequate transparency for efficient light transport. Scintillation performance was then evaluated using an alpha source. Comparison with a commercial plastic scintillator benchmark highlights the potential of the proposed nanocomposite for advanced and customizable dosimetry applications, especially where flexible detector geometries and particle discrimination are required.

Methylpiperazinium Perovskitoid for High-Performance X-Ray Detection (#2343)

Hong Li

wuhan university of technology, HuBei, China

This work was financially supported by the Guangdong Major Project of Basic and Applied Basic Research (grant no.2021B0301030001), National Natural Science Foundation of China (U2330115.62275206).

Abstract

Abstract — Metal halide perovskites are promising for direct X-ray detection, but phase impurity in conventional quasi-2D systems limit device performance. Here we report a methylpiperazinium (MPZ) based quasi-2D perovskitoid, $(mpz)_5Pb_8Br_{26}\cdot 2H_2O$. The crystal features a unique segmented architecture: four corner-sharing $PbBr_6$ octahedra form 3D-like conduction blocks, separated by 2D spacer regions where MPZ^{2+}. This design simultaneously achieves a high mobility-lifetime ($\mu\tau$) product of 6.1×10^{-3} cm^2 V^{-1}. A direct X-ray detector fabricated in the out-of-plane configuration exhibits a sensitivity of 33.18 μC Gy^{-1} cm^{-2} and a detection limit of 6.2 nGy s^{-1}, representing a record among lead-based quasi-2D perovskites. The successful construction of quasi-2D single crystals provides a versatile platform for high-performance optoelectronics, proving its efficacy for applications spanning photodetection, solar energy conversion, and light-emitting devices even under the most rigorous material requirements

Design and Evaluation of Graphene Strip Arrays for Radiation Detection (#2400)

Marcos Turqueti[1], Alec Lindman[2], Alan Poon[2]

[1] Lawrence Berkeley National Laboratory, Engineering Division, Berkeley, USA; [2] Lawrence Berkeley National Laboratory, Nuclear Science, Berkeley, USA

Abstract

Graphene has emerged as a promising material for next-generation sensing systems due to its exceptional carrier mobility, low electronic noise, mechanical flexibility, and high electrical conductivity. In this work, we present the design and evaluation of graphene strip arrays for radiation detection applications. The detector architecture employs segmented graphene sensing strips integrated connected to low-noise front-end electronics to investigate radiation-induced signal generation, spatial sensitivity, and charge transport characteristics. Conventional semiconductor radiation detectors often face challenges associated with fabrication complexity, radiation damage, and limitations in scaling toward lightweight and flexible detection systems. Graphene-based detectors provide an alternative approach with potential advantages in fast signal response, compact integration, and scalable fabrication.

The proposed detector consists of patterned graphene strip arrays fabricated on an silicon substrate with optimized strip geometry and differential signal readout. Radiation-induced charge variations are detected through low-noise charge amplification and signal conditioning electronics. Preliminary experimental characterization demonstrates measurable detector response under controlled irradiation conditions and stable electrical operation across multiple bias configurations. The segmented strip geometry enables position-sensitive radiation detection and supports scalability toward larger-area detector systems. The presented work demonstrates the feasibility of graphene strip arrays as compact, low-noise radiation detectors for advanced nuclear science and charged-particle instrumentation.

Geometry-Defined Impact Ionization in Two-Stage Mesa-Type Silicon Electron Multipliers (#1064)

Hironori Sonobe, Naoki Kamiya, Tatsuya Kobayashi, Ryozo Shiozaki, Yusuke Matsunaga

Hamamatsu Photonics K.K., Solid State Division, Hamamatsu, Japan

Abstract

A silicon electron multiplier (SiEM) that achieves internal multiplication without a dedicated doped gain layer is demonstrated. The device employs a two-stage mesa-type architecture in which impact ionization occurs in a localized high-field region formed by geometric field crowding within a cylindrical mesa. A buried gate electrode independently controls carrier injection into the multiplication region. Devices were fabricated in a sub-micron CMOS process line. The structure consists of an injection stage and a multiplication stage. The injection stage uses a buried polysilicon gate to electrostatically steer carriers toward the center of the pixel, while the multiplication stage confines the high electric field within a constricted cylindrical mesa. Three-terminal operation enables independent control of multiplication through the gate bias. Electro-optical measurements were performed using 905 nm illumination with an absorption depth of approximately 30–35 μm in silicon. The devices exhibit a multiplication factor exceeding 100 for |Vgate| < 50 V. Scaling of the cylindrical mesa geometry shows that smaller diameters and reduced mesa height lower the bias required for multiplication. For example, reducing the mesa diameter from 3.0 μm to 1.6 μm increases the multiplication factor from approximately 1.5 to greater than 3 at |Vgate| = 40 V, and gains exceeding 400 are obtained at |Vgate| ≈ 50 V. Temperature measurements from −40 °C to 40 °C show a multiplication sensitivity of dVgate/dT = 24–30 mV/°C at constant gain (M = 10). This value is significantly smaller than those typically reported for gain-layer detectors. These results demonstrate geometry-defined impact ionization with electrostatically controlled carrier injection. The proposed SiEM provides a design framework for radiation-tolerant silicon detectors with internal multiplication.

Abstract

Thin segmented silicon sensors have attracted increasing interest for beam monitoring and microdosimetry in emerging radiotherapy modalities such as FLASH and spatially fractionated radiotherapy, owing to their excellent temporal response, high spatial precision, and robustness. In this study, thin planar silicon sensor manufactured by Fondazione Bruno Kessler and implementing different electrode-isolation strategies were investigated through electrical characterization and irradiation tests under ultra-high dose rate electron beams. The investigated devices included sensors with two different trench technologies, which were compared with segmented silicon detectors based on p-stop and Junction Termination Extension isolation techniques. Electric characterization was performed through current-voltage and capacitance-voltage measurements to extract relevant operational parameters. In addition, the detectors were exposed to electron beams delivered by a LINAC at dose-per-pulse values of 2.2 Gy in a 4μs pulse. Preliminary results showed comparable electrical performance for all detector technologies, with leakage currents in the nanoampere range and stable operation up to 200 V bias voltage. Nevertheless, segmented sensor without trench isolation exhibited deviations between collected charge and pad areas ratios, suggesting geometry-dependent contributions to charge collection, likely related to perimeter effects. Ongoing studies aim to evaluate whether trench isolation mitigates these effects and improves sensitive volume definition, as well as to assess the radiation hardness of the proposed detector technologies.

This work was supported in part by the National Natural Science Foundation of China under Grant 12375188 and in part by the National Key Research and Development Program of China under Grant 2023YFF0719600.

Abstract

In this work, a novel 3D column-trench detector based on a 30 $\mu $m thick high-resistivity P-type epitaxial silicon is proposed and experimentally validated. The detector is fabricated on the standard CMOS process platform of the Institute of Microelectronics, Chinese Academy of Sciences (IMECAS), featuring a hybrid 3D configuration that combines N-type column electrodes and P-type strip trench electrodes. Electrical characterizations performed on single-pixel device with central N-type electrode demonstrate that the proposed detector achieves a low leakage current of 0.3 nA and a small capacitance of 0.3 pF under a reverse bias voltage of 30 V. According to the analysis of current-voltage (IV) and capacitance-voltage (CV) characteristics, the device exhibits a full depletion voltage of approximately 3 V and a high breakdown voltage up to 130 V. In addition, the device design, layout, and electrical performance of the 3DCTS are systematically elaborated in this paper. The electrical test results indicate that the proposed device possesses promising application prospects in high-energy physics experiments, medical imaging, and space radiation detection.

Large-Area Silicon Pixel Sensor Processing on 8-Inch High-Resistivity Wafers (#2906)

Juha Kalliopuska, Jussi Marles, Sampson Andoh, Mikko Ilosalo, Naresh Giri, Olena Shtepura, Magdalena Järvenpää, Sami Vähänen

ADVAFAB, Helsinki, Finland

Abstract

The transition from 6-inch to 8-inch high-resistivity silicon wafer processing has been implemented for the fabrication of large-area pixel sensors for photon-counting applications. The upgraded production line enables a doubling of usable wafer area compared to conventional 6-inch wafers, allowing either larger sensor formats or increased number of sensors per wafer. Prototype 8- inch wafers were processed using stepper lithography with stitching to realize multiple sensor layouts compatible with Medipix3, Timepix3 and Timepix4 readout ASICs. Electrical characterization was performed prior to under-bump metallization (UBM) and flip-chip assembly. Leakage currents at a reverse bias of -300 V were compared with reference data from 6-inch production batches of 500 µm thick sensors. An approximately 60% increase in leakage current for sensors fabricated on 8-inch wafers is attributed to a non-uniform radial resistivity distribution observed in the prototype 8-inch material.

8-inch wafer processing has been successfully demonstrated for silicon pixel sensor fabrication. The process is compatible with existing 6-inch technology and supports large-area sensor production. Although an increased leakage current was observed due to resistivity non-uniformity, the results confirm the feasibility of the approach. Future 8-inch production wafers are expected to have an improved resistivity profile, which is anticipated to reduce the leakage current and improve sensor uniformity.

Abstract

This contribution will present the first results on the radiation resistance of p-in-n Low-Gain Avalanche Diodes (nLGAD) produced at Fondazione Bruno Kessler (FBK), where signal multiplication is achieved through a high-concentration n-type dopant implant. The sensors are fabricated on thin epitaxial n-type substrates with an active thickness of 55 µm and incorporate a redesigned p^{++} ohmic contact and n^{+} gain layer, optimized to account for dopant activation and diffusion effects. Fourteen wafers were produced, exploring different implant depths, diffusion profiles, and employing two n-type dopants, Phosphorus and Arsenic. These devices provide a unique platform to study the donor removal mechanism at concentrations of ~10^{16} atoms/cm³, offering key input for the development of radiation-hard p^{+}–n^{+} compensated LGADs for operation at extreme fluences. We will present the first results on nLGAD sensors irradiated with neutrons in the fluence range 10^{14}–10^{15} n_{eq}/cm². The characterization pre- and post-irradiation focuses on the evolution of gain and charge collection, providing a first direct assessment of the radiation hardness of nLGAD in this fluence regime. The study of the radiation resistance of the gain layer will be further supported by the characterization of the n^{+} implant, through the characterization of irradiated Van der Pauw structures.

Abstract

Recent progress in sensor technology has paved the way for high-resolution 4D-tracking silicon detectors capable of simultaneously measuring position and time of passage of charged particles. This is achieved through the innovative concepts of Low Gain Avalanche Diodes (LGAD) and Resistive Silicon Detectors (RSD). While standard LGADs aim at excellent temporal resolution, the RSD design also achieves high spatial resolution through signal sharing. This contribution presents the latest advancements in the DC-coupled RSD (DC-RSD) design, which utilizes trenches for cell isolation and signal sharing control. A major milestone of the 2026 campaign is the integration of the FAST3 ASIC, a custom-designed chip specifically optimized for high-precision timing measurements with LGAD-based sensors. For the first time, this readout electronics is employed to characterize the performance of DC-RSD sensors in a test beam environment before and after radiation exposure. We will present the results of an experimental campaign conducted on DC-RSD sensors irradiated at fluences 2×10^{14} and 4×10^{14} neq/cm². These measurements will represent the first test beam characterization performed on irradiated DC-RSD sensors. The analysis focuses on the evolution of timing and spatial resolution as a function of fluence,

comparing the performance of the FAST3 chip with previous readout solutions. The results, obtained at the DESY and CERN test beam facilities, offer insights into the radiation hardness and robustness of the DC-RSD principle.

Abstract

Ultra-low-count SPECT imaging in alpha-particle radiopharmaceutical therapy (α-RPT) remains challenged by low administered activities and severe noise amplification associated with conventional reconstruction. We propose a fully three-dimensional diffusion posterior sampling (3D-DPS) framework for physics-informed SPECT reconstruction integrating learned generative priors with a Poisson-consistent likelihood formulation for emission tomography. A 3D unconditional diffusion model was trained on PSMA PET volumes to learn tracer uptake distributions. To further constrain the inverse problem, patient-specific prior adaptation was introduced through synthetic subject-specific uptake realizations designed to model physiologically plausible tracer variability during training. During reconstruction, the learned priors are coupled with a physics-based SPECT forward model through a Poisson log-likelihood formulation consistent with MLEM reconstruction. Validation was performed using realistic ultra-low-count ^{225}Ac-PSMA simulations, as well as two clinical ^{177}Lu-PSMA SPECT acquisitions retrospectively degraded to mimic ^{225}Ac imaging conditions using Poisson thinning (~10^5 detected photons) and angular downsampling (120 to 30 projections). Compared with MLEM and regularized MLEM, the proposed framework reduced reconstruction error (NMAE = 0.34 ± 0.04 versus 0.53 ± 0.02 and 0.41 ± 0.05, respectively) and improved structural similarity (SSIM = 0.90 ± 0.05 versus 0.77 ± 0.13 and 0.85 ± 0.08, respectively) while preserving anatomical detail and projection-domain consistency. Reconstructions from degraded clinical acquisitions demonstrated substantially improved noise suppression and lesion preservation compared with conventional reconstruction. These results demonstrate the potential of diffusion-based reconstruction for quantitative ultra-low-count SPECT imaging and α-RPT dosimetry.

Abstract

Respiratory motion and attenuation mismatch degrade positron emission tomography (PET) reconstruction. Furthermore, the additional scan required for attenuation correction (AC) may complexify the imaging workflow and increase radiation exposure. Joint reconstruction of activity and attenuation with motion estimation (JRAAM) methods address these issues by jointly estimating activity, attenuation, and motion solely from emission data. We propose JRAAM-DPS, a diffusion model (DM)-based framework that leverages a diffusion prior on activity–attenuation image pairs to recover motion-compensated and attenuation-corrected PET images directly from respiratory-gated PET data. We evaluated the proposed method on simulated data, and demonstrated improved image quality compared to maximum likelihood activity and attenuation (MLAA) and the non-motion-corrected JRAA-DPS

A. Hammers is with the King's College London & Guy's and St Thomas' PET Centre.

Abstract

Flow-based generative models can be used as pre-trained priors for inverse problems; however, their use in PET image reconstruction remains largely unexplored. We present a proof-of-principle study using flow priors for 2D PET reconstruction. A U-Net was trained by flow matching on simple brain phantoms and used as an unconditional image prior. We used the MPC-Flow (Model Predictive Control) framework to condition the pre-trained flow via direct control of the generative dynamics, and adapted it to the PET setting by incorporating a Poisson likelihood and an explicit intensity scaling to address the dynamic range mismatch between the generative model and PET data. This method was used to reconstruct images from simulated low-count PET sinogram data. On held-out phantoms, MPC-Flow achieved lower error than diffusion-based reconstruction and conventional iterative baselines, likely due to the explicit control objective, which balances likelihood maximization with a penalty on deviations from the learned flow trajectory. These results demonstrate that flow priors can be coupled with PET likelihoods in a principled framework. Evaluation on more realistic anatomical phantoms and clinical data, where the learned manifold may be less accurate, will be a necessary next step.

Flow Matching for PET Image Reconstruction (#1731)

Fumio Hashimoto, Ziqian Huang, Kuang Gong

University of Florida, Gainesville, USA

Abstract

Generative models, especially diffusion models, have recently demonstrated strong potential for positron emission tomography (PET) image reconstruction. However, diffusion models often require many sampling steps and incur a high computational cost, which may limit their practical use in PET image reconstruction. Flow matching is an attractive alternative, enabling continuous generative modeling with a simpler sampling procedure and a stable, efficient training framework. In this study, we present flow matching-based PET image reconstruction methods. We first establish PET-FlowDPS as a baseline by incorporating Poisson likelihood guidance into the FlowDPS framework. We then propose a model-based PET image reconstruction method that uses a pretrained flow matching model as a prior. The proposed reconstruction method iteratively performs three steps: (1) flow-based destination estimation to obtain a clean image estimate, (2) penalized PET image reconstruction refinement to enforce data consistency, and (3) flow-based propagation to update the image to the next time step. The proposed reconstruction method was evaluated using 10 low-dose clinical brain [^{18}F]FDG datasets. Experimental results showed that the flow matching-based methods reduced image noise while preserving cortical structures compared with the maximum *a posteriori* expectation-maximization (MAPEM) algorithm. The proposed method further improved image quality compared with PET-FlowDPS in terms of PSNR. In addition, the computation time of the proposed method was less than 2 minutes. These results demonstrate that flow matching is a promising generative prior for PET image reconstruction.

Data-Driven Kernel EM Reconstruction Using Attention-Based Learning for Dynamic PET (#3168)

Haoran Chang[1], Wenyuan Qi[2], Jeff Kolthammer[2], Jinyi Qi[1]

[1] University of California, Davis, Biomedical Engineering, Davis, USA; [2] Canon Medical Research USA, Vernon Hills, USA

Abstract

Dynamic positron emission tomography (PET) reconstruction remains challenging due to low count statistics in individual frames and the ill-posed nature of the inverse problem. Kernelized expectation maximization (KEM) methods have been developed to incorporate prior information through a kernel matrix; however, their performance strongly depends on the design of the kernel and the prior information, as well as the associated hyperparameters. In this work, we propose a data-driven framework for kernel construction based on attention-guided learning from dynamic PET images.

A neural network is used to learn spatial-temporal relationships from dynamic image frames, producing attention maps that encode pairwise similarities. These features are further analyzed via dimensionality reduction and clustering to identify regions of interest (ROIs) with similar spatial-temporal characteristics. The resulting ROI masks are used to define adaptive neighborhoods and compute kernel weights, producing a data-driven kernel that is subsequently integrated into the KEM reconstruction framework.

Experiments on simulated data demonstrate that the proposed method not only improves image quality but also enables accurate estimation of time-activity curves (TACs) across different ROIs. In real PET data, the method achieves enhanced reconstruction quality, while exhibiting reduced sensitivity to the choice of clustering parameters compared with the baseline approach that performs clustering directly on the dynamic PET images without attention-guided learning. In particular, stable reconstruction performance is maintained across a wide range of cluster numbers, whereas baseline approaches show strong parameter dependence and introduce noticeable noise at larger cluster sizes.

These results demonstrate that attention-based kernel learning provides a robust and effective strategy for improving dynamic PET reconstruction quality and quantitative accuracy.

Abstract

Awake functional brain imaging is crucial for behavioral neuroscience, but conventional preclinical PET scanners typically require anesthesia, which suppresses brain glucose metabolism and limits natural behavioral studies. To address these limitations, we developed Gym-PET, a 75 g head-mounted wearable PET system optimized for awake running mice.

The wearable module features a compact detector ring (20.0 mm inner diameter) composed of 1 x 1 x 5 mm³ LYSO crystal arrays coupled to SiPMs, a short crystal design chosen to minimize parallax degradation under close-range conditions. To enable stable imaging during locomotion, the scanner is integrated with a customized treadmill platform using a lightweight suspension mechanism. Based on the NEMA NU-4 2008 standard, the system achieved 12.5% energy resolution, 0.8% peak sensitivity, and a high spatial resolution of 0.66 mm. Compared to conventional preclinical PET systems, Gym-PET demonstrated visibly improved delineation of small subcortical structures.

To validate the system's in vivo capabilities, dynamic 18F-FDG PET imaging was performed. The results successfully captured exercise-induced metabolic activation in the brainstem and thalamus of awake running mice. Furthermore, a three-day sleep deprivation study revealed the system's sensitivity to global metabolic suppression without anesthesia interference. Ultimately, the Gym-PET platform significantly reduces anesthesia-related metabolic interference, establishing a highly effective tool for high-resolution molecular neuroimaging in awake behavioral models.

Abstract

This study introduces Flexible On-demand Customized Ultra-resolution System for PET (FOCUS-PET), a novel technique designed to maximize spatial resolution and counting statistics within a predefined region of interest. The efficacy of FOCUS-PET was rigorously evaluated via Monte Carlo simulations and physical experiments using high-resolution add-on detector configurations. The simulated system employed an arc-shaped add-on detector comprised of a 4×2 module array, with each module housing 32×48 LYSO crystals (0.42×0.42×5.0 mm³). Sensitivity profiles were mapped using an axially stepped ^{22}Na point source, and a three-bed whole-body protocol was simulated utilizing a micro-Derenzo phantom. Simulation results demonstrated a 5.1% to 19.8% enhancement in absolute sensitivity. The system resolved 0.9-mm micro-rods, effectively surpassing native resolution limits, and improved the peak-to-valley ratio (PVR) and contrast recovery (CR) for 1.0-mm rods from 1.50 to 2.13 and 33.30% to 52.95%, respectively. Experimental validation was performed by integrating a flat-panel add-on detector—comprising two modules with 44×44 LYSO arrays (0.52×0.52×5.0 mm³)—into an ACTIVE 7 MAX preclinical scanner. Imaging of a physical Derenzo phantom was conducted to assess ultimate resolution and multi-bed stitching fidelity. Physical experiments corroborated the theoretical gains, with the flat-panel FOCUS-PET device consistently improving PVR (1.57 to 1.90) and CR (27.93% to 33.19%) for 1.25-mm hot rods compared to the baseline. In conclusion, FOCUS-PET significantly elevates system sensitivity and spatial resolution, providing a cost-effective pathway for ultra-high-resolution preclinical imaging and potential translation to clinical whole-body PET applications.

Abstract

High spatial resolution is essential to resolve small structures in the brain and to enable imaging of neurological pathways at the onset of diseases. A key challenge with ultra-high-resolution (UHR) PET scanners is the significant degradation of resolution that occurs beyond the central area of the field-of-view (FOV). The UHR Brain PET scanner was designed with short (12 mm) LYSO crystals to mitigate the parallax error off the FOV center, but at the expense of reduced sensitivity. To address these limitations, the LabPET II technology platform was upgraded to implement depth-of-interaction (DOI) measurement using longer (15 mm) dual LGSO phoswich detectors in the SAVANT. Simulation results indicate an estimated 40% gain in sensitivity, while maintaining the resolution below 2 mm FWHM at the edge of the brain. For DOI determination, the crystal identification between *slow* (43-48 ns decay time) and *fast* (30-35 ns decay time) LGSO scintillators uses a model-based dual-threshold time-over-threshold (ToT) discrimination technique, currently achieving better than 70% accuracy. The 6.5/8.5 mm length ratio of the top *slow* and bottom *fast* LGSO scintillators resulted from trade-offs between off-center spatial resolution and balanced coincidence detection efficiency of the two crystal layers. We report the initial experimental characterization of the partially assembled scanner (182 mm axial extent), which demonstrate the improvement in sensitivity and resolution uniformity across the radial FOV achieved using this simple DOI discrimination scheme. Point source and phantom measurements taken at various radial positions demonstrate the gain in spatial resolution compared to non-DOI measurements, though not reaching the resolution predicted by simulation. Further refinement of the crystal identification process using AI-based classification is expected to yield the forecasted benefits from simulation. Preliminary results for imaging the human brain will be presented.

A Physics-Guided Deep Learning Method for Fast System Matrix Modeling in Self-Collimating SPECT Using Sparse Point-Source Calibration (#2412)

Qiqi Ye[1], Debin Zhang[1], Huidong Xie[2], Zhenlei Lyu[1], Tianyu Ma[1]

[1] *Tsinghua University, Beijing, China;* [2] *Fudan University, Shanghai, China*

Abstract

Self-collimating SPECT (SC-SPECT) enables simultaneous high-resolution and high-sensitivity imaging using sparse-scintillator detector layers. Accurate system matrix (SM) estimation is essential but remains challenging in SC-SPECT, because dense point-source calibration is time-consuming and conventional modeling is limited by complex system physics, while geometry-dependent detector responses further complicate AI-based sparse-to-dense recovery. In this work, we propose a physics-guided sparse-to-dense SM modeling framework to recover the full SM from 10k point-source measurements. The framework uses a customized 3D encoder–decoder with anisotropic convolutions and modified down/up-sampling to preserve fine structures under limited sampling. Sparse response intensity, sampling positions, and detector angular information are encoded as four input channels, while LOR-directional profile and curvature-continuity losses enforce physically consistent recovery. The model is trained on simulated PPDFs, with ablation studies evaluating the input-channel, architecture, and loss designs. It is further validated using experimental SM-level metrics and MLEM reconstructions of hot-rod phantom and small-animal data. Results demonstrate improved PPDF recovery and reconstruction quality over interpolation-based SM estimation and a standard U-Net, while reducing the calibration time by over 97.5%.

BuckyPET: Performance Evaluation and NEMA Adaptation for Compact PET Geometries (#3115)

David Perez-Benito[1], Luis Batres[1], Lidia Jimenez Algarra[1], Marcos Vidal[1], Juan J. Vaquero[1,2]

[1] Universidad Carlos III de Madrid, Departamento de Bioingeniería, Madrid, Spain; [2] Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Abstract

Dedicated brain PET systems are attracting renewed interest due to their potential to overcome key limitations of conventional whole-body PET, particularly limited sensitivity and spatial resolution for neurological imaging. In this work, we present BuckyPET, an innovative dedicated brain PET scanner inspired by fullerene-like geometry. The system is based on 234 regular hexagonal LYSO detector modules arranged to closely approximate a spherical configuration, arguably the most efficient geometry for brain PET imaging. Each detector is laser-engraved to create customizable optical barriers defining hexagonal scintillation pixels and is coupled to a hexagonal Hamamatsu MPPC with 61 individually read channels.

Current clinical and preclinical NEMA standards rely on concepts such as sinograms, single-slice rebinning, axial axes, and transaxial planes, which are not directly applicable to spherical or highly enclosed geometries. We also discuss the need for a modified NEMA NU 2-2018-like protocol for non-cylindrical PET systems. We propose preserving the core performance metrics of the standard while reformulating the analysis in a geometry-independent framework.

Preliminary results demonstrate the high-sensitivity capabilities of BuckyPET, alongside a high noise-to-count ratio and spatial resolution in the range of 1.5-2 mm. Ongoing work focuses on fine-tuning the electronics and acquisition system and assessing robustness under different operating conditions. Thus, the final figures of merit are expected to further improve, while ongoing advances in the reconstruction framework are anticipated to push the spatial resolution beyond the 1 mm frontier. First studies for the clinical validation are scheduled for summer 2026.

SPECT Reconstruction via Diffusion Sampling from a PET Image Manifold for Theranostics (#1954)

Huanzhe Wei[1], Lefteris Livieratos[1,2], George Webber[1], Andrew J. Reader[1]

[1] Kings College London, School of Biomedical Engineering and Imaging Sciences, London, UK; [2] Kings College London, Guy's and St Thomas' NHS Foundation Trust, London, UK

Abstract

Single photon emission computed tomography (SPECT) remains the standard modality for uptake verification and patient-specific dosimetry in molecular radiotherapy (MRT), however it has limited spatial resolution and noise characteristics compared to pre-therapy positron emission tomography (PET). Existing approaches that incorporate PET priors into SPECT reconstruction are often constrained by hand-crafted feature representations and suffer from inter-modality mismatch and registration-induced artifacts. In this work, we employ a conditional generative framework to enhance SPECT reconstruction toward PET-level image quality. A denoising diffusion probabilistic model (DDPM) is trained to learn the distribution of high-quality PET images. During inference, the reverse diffusion process is conditioned on measured SPECT data and CT images, enabling anatomically consistent, high-fidelity image synthesis. The method is initially assessed using 2D Zubal phantom simulations. Performance is compared with conventional maximum likelihood expectation maximization (MLEM) and kernel based methods. Both quantitative metrics and qualitative analysis demonstrate that the diffusion-based approach achieves enhanced edge preservation and superior noise suppression. The reconstructed images show closer agreement with reference data compared to MLEM and kernel based reconstructions. By avoiding explicit PET–SPECT registration, the framework mitigates spatial misalignment and associated artifacts. These results indicate that conditional diffusion sampling provides a principled and flexible approach to improve resolution and noise limitations in SPECT, with potential to improve quantitative accuracy in MRT applications.

Abstract

^{90}Y bremsstrahlung SPECT imaging remains challenging due to its broad continuous energy spectrum. In this study, we proposed and evaluated a novel event-by-event energy-dependent list-mode reconstruction algorithm for quantitative ^{90}Y bremsstrahlung SPECT. To enable real-time and reasonably accurate energy-dependent collimator-detector response modeling, we proposed and incorporated a True Half-Width method into the list-mode reconstruction framework. Monte Carlo simulations were performed using three energy windows: 90-160 keV, 105-285 keV, and 90-400 keV. Quantitative evaluation was performed using contrast recovery coefficient and background variability. Compared with projection-based reconstruction, list-mode reconstruction achieved the best quantitative performance using the 90-400 keV energy window, owing to accurate event-level energy-dependent system matrix modeling over the broad continuous energy spectrum. These results demonstrate that event-by-event energy-dependent list-mode reconstruction is essential for improving the quantitative accuracy of ^{90}Y bremsstrahlung SPECT.

Introducing “T-Index”—A Metric for Quantifying Data Range and Sampling Sufficiency (#2039)

Katsuyuki Taguchi, Jingyan Xu

Johns Hopkins University, Baltimore, USA

The work has been supported by NIH grants R01 NS126256, U01 EB037558, R01 EB036984, R21 EB034337, R21 EB033426, R21 EB037806.

Abstract

Many image reconstruction methods for x-ray computed tomography (CT) use optimization approaches with cost functions that consist of a data fidelity term and a prior term. Extensive efforts have been devoted to construct better priors, some using machine learning, for high resolution, low dose, and spectral imaging. There seems to be a belief that a good prior can overcome any problems in data acquisition, downplaying the data fidelity term. It would be desirable if we could quantify the sufficiency of the problem setting (or adequacy of the data acquisition) toward a set of desired imaging properties. We propose “Truth index” or “T-index” to quantify data range and data sampling issues in this work. When fully developed, the T-index will show, independent of specific image reconstruction methods used, how much the solution can be trusted or has a risk of hallucination.

Abstract

X-ray time of flight information can be used in computed tomography to characterize photon interactions and discriminate scattered from unscattered events. Specifically, photons undergoing Compton and Rayleigh scattering are subject to trajectory deviations that increase their path length relative to primary photons. Therefore, with adequate temporal resolution, scattered photons are detected with larger time delay with respect to primary photons, providing a physically grounded mechanism to reject scatter. Recent technological developments in ultra-fast X-ray sources (e.g: 50ps) and high-temporal-resolution photon-counting detectors may allow for this imaging modality.
In this work, Monte Carlo (MC) simulations of a water cylinder were performed assuming Gaussian source pulse shape and detector timing jitter, with combined full-width-half-maximum as low as 50ps. A threshold-based scatter rejection method was applied, sweeping multiple thresholds to find the optimal balance between scatter rejection efficiency (η) and primary retention (ε). Filtered-backprojection reconstructions were performed and evaluated in terms of root mean square error and bias. Rejection performances were compared with an ideal, MC-based scatter subtraction technique, that leverages template fitting to estimate the average scatter contribution from time-delay histograms. A combined rejection-subtraction approach was also evaluated.For rejection only, the optimal reconstruction accuracy is obtained with a threshold T'=30 ps, corresponding to η=59% and ε=80%. Residual scatter leads to bias in the reconstructed attenuation, preventing the method from achieving the same reconstruction accuracy as the ideal subtraction. However, rejection yields lower noise levels compared to subtraction. Combining rejection and subtraction may provide a better compromise between bias and noise.

This work was supported in part by Siemens Healthineers. The product/feature and/or service offerings mentioned herein are not commercially available in all countries and/or for all modalities. Their future availability cannot be guaranteed.

Abstract
We quantify the impact of scatter on the performance of bone suppression in virtual non-calcium chest radiographs (VNCa-CXR) generated with (i) a multi-layer flat-panel detector (ML-FPD, three 200-um thick CsI layers) and (ii) with a kV-switching protocol (60/140 kVp). We show that in the setting of log-subtraction, the decomposition weight (DW) can be adjusted for scatter-to-primary ratio (SPR) such that the scatter-induced bias in VNCa is locally corrected (scatter-compensating weight, DW-scat). However, DW-scat is spatially varying. If a constant DW is used in log-subtraction, the magnitude of bone residual in VNCa radiographs will depend on the degree of spatial

inhomogeneity in DW-scat. We investigate this effect is simulation studies in anthropomorphic chest phantoms (20 – 24 cm thickness) with and without an anti-scatter grid (ASG). Without a scatter-compensating DW, scatter-induced bone residual increased by >100% is most configurations except for ML-FPD with a grid. Applying DW-scat averaged over central lung region reduced the residual by up to 50% for ML-FPD without an ASG and by ~40% for kV-switching with an ASG. Overall, our results reveal that DE VNCa imaging is relatively robust to scatter in scenarios with a grid, where kV-switching appears to benefit from spatially-averaged scatter-compensating DW more than ML-FPD, likely due to differences in scatter content of the two energy channels. Without a grid, both configurations may require a spatially-dependent scatter compensation for optimal bone suppression.

Unrolled relaxed algorithm for 3D SPECT reconstruction (#2388)

Corentin Constanza[1], David Sarrut[1], Ane Etxebeste[1,2]

[1] CREATIS, CNRS UMR 5220; INSERM U 1044, Université de Lyon; INSA-Lyon; Université Lyon 1, Villeurbanne, France; [2] Centre de lutte contre le cancer Léon-Bérard, Lyon, France

Abstract

In this work, we propose an unrolled Block Sequential Regularized Expectation Maximization (BSREM) reconstruction framework in which the gradient of the regularization term is learned using a convolutional neural network. Building on our previous work, we adopt Jacobian-Free Unrolling (JFU) to enable memory-efficient training on 3D synthetic data. This training strategy backpropagates only through the final iteration of the unrolled optimization, significantly reducing memory consumption while improving training stability. We investigate the influence of relaxation strategies within the unrolled BSREM scheme and analyze their impact on convergence behavior, stability, and reconstruction quality. Experiments conducted on realistic simulated SPECT datasets and clinical ^{177}Lu-DOTATATE patient data show that JFU-based unrolling consistently outperforms classical unrolled training for an equivalent number of parameters and memory usage. Unlike classical unrolling, which requires strong relaxation to ensure stable training, JFU achieves optimal performance with weak or no relaxation. Excessive relaxation is shown to be suboptimal, leading to reduced quantitative accuracy. Quantitative evaluations demonstrate improvements in both global image quality and organ-level activity accuracy compared to OSEM and conventional BSREM with a Relative Difference Penalty prior. As observed in our previous study using Green's one-step-late algorithm, the proposed approach may introduce over-separation artifacts between regions of low and high activity. This behavior appears intrinsic to learning the regularization gradient rather than to the unrolling strategy itself. Overall, this work highlights the advantages of Jacobian-Free Unrolling for scalable and stable learning-based SPECT reconstruction and provides insights into the role of relaxation in unrolled optimization schemes.

Abstract
Positron emission tomography provides functional images from two-photon coincidences. In human tissue, approximately 40% of annihilations are preceded by positronium formation, of which the ortho-positronium component partially decays into three photons [1]. This three-photon channel carries additional information about the local micro-environment [1], including the three-to-two-photon yield ratio as a potential diagnostic marker [3,2], and its exploitation does not require a prompt photon, making it compatible with standard radionuclides such as FDG. We propose the Three-Photon Bayesian Imaging of Ortho-Positronium algorithm, a novel event-by-event reconstruction method formulated as a Bayesian maximum a posteriori inference problem, which unifies time-based trilateration [4], energy-based reconstruction [3], and a physics-informed prior derived from the quantum electrodynamics description of ortho-positronium decay [5-6] within a single probabilistic framework. Monte Carlo simulations modelled after the Siemens Biograph Quadra scanner [7] demonstrate an improvement of a factor of two over time-based trilateration and by an order of magnitude over energy-based reconstruction. The proposed

approach is compatible with existing scanners capable of registering three-photon coincidences, broadening its applicability beyond positronium lifetime imaging to standard clinical radionuclides.

Lutetium-176-Aided Joint Activity and Attenuation Reconstruction in TOF-PET Using Trust-Region Cubic Surrogate Optimization (#2772)

Xin Zhao, Zhijun Zhao, Zhao Wang, Zhaoheng Xie

Peking University, Beijing, China

This work was supported by National Natural Science Foundation of China (62394311) and National Biomedical Imaging Facility Grant.

Abstract
Joint Maximum Likelihood Activity and Attenuation (MLAA) provides a promising CT-less attenuation correction framework but suffers from global scaling ambiguity. Intrinsic Lu-176 background radiation provides patient-specific transmission information to reduce this issue, while introducing a highly nonlinear and ill-conditioned joint likelihood. We propose the Separable Cubic Surrogate with Trust Region (SCS-TR) algorithm, utilizing an analytical Lipschitz constant and a vectorized solver to ensure strictly monotonic convergence and avoid local optima. The reconstruction is initialized with Maximum Likelihood Transmission Reconstruction (MLTR) results. GATE simulations studies demonstrate that SCS-TR effectively recovers clear bone structures and smooth uniform regions without explicit regularization. The proposed method recovered clear bony structures and uniform soft-tissue regions without explicit regularization, and maintained structural fidelity under 20% count statistics.

Abstract

Total-body positron emission tomography (TB-PET) provides significantly improved sensitivity, enabling ultra-short time framing for dynamic imaging. However, the resulting low count statistics lead to increased noise and unstable time activity curves (TACs), limiting quantitative accuracy. We investigate a kernel-based reconstruction approach within a list-mode (LM)-derived synthetic framework, where a vendor reconstruction is forward projected through an event-specific LM system matrix to generate synthetic data, implicitly includes attenuation, normalisation, scatter, and randoms effects while enabling flexible algorithm design.

Spatial, temporal, and spatio-temporal kernels are evaluated for short-frame FDG data acquired on a Biograph Vision Quadra system, with features constructed from multiple dynamic intervals. Reconstructions are compared with a 10x higher count vendor reference images using spatial and temporal PRMSE. Spatially, the spatio-temporal kernel achieves the lowest error. In addition, we demonstrated that kernel methods benefit from larger neighbourhoods resulting in improved visual quality compared to synthetic PET. This was computationally feasible on consumer hardware by using region-of-interest specific reconstructions.

These results demonstrate that LM-derived synthetic kernel reconstruction provides a flexible framework for incorporating spatial and temporal priors in TB-PET. While performance is currently limited by kernel parameter selection, the observed improvements in spatial and temporal behaviour indicate strong potential for optimisation through tuning the kernel strength and feature vector design.

Abstract

Micro X-ray computed tomography (micro-CT) enables non-destructive visualization of fine internal structures. Resolving finer details requires higher geometric magnification, typically achieved by reducing the source-to-rotation-center distance (SRD). However, short-SRD acquisition can suffer from a limited angular range due to physical interference with the X-ray source and from projection truncation when the object extends beyond the field-of-view (FOV), causing streak artifacts and structural distortions. Supervised learning-based reconstruction methods have been investigated to mitigate such artifacts but applying them to non-destructive high-magnification micro-CT is difficult because fully sampled, non-truncated reference data cannot be readily acquired without destructive sample preparation. Moreover, many existing methods are designed for 2D fan-beam geometry rather than 3D cone-beam geometry commonly used in micro-CT. We propose an unsupervised reconstruction method that simultaneously reduces limited-angle and projection-truncation artifacts by incorporating long-SRD measurements. Long-SRD acquisition provides full-view, non-truncated projections, albeit at lower spatial resolution, complementing the high-resolution but incomplete short-SRD acquisition. By jointly using these complementary measurements, the proposed method preserves fine structural details while recovering the global object structure without requiring ground-truth images. Numerical experiments demonstrated that the proposed method reduced streak artifacts and recovered structural information outside the short-SRD FOV. To the best of our knowledge, this is the first unsupervised 3D cone-beam reconstruction method to simultaneously address both artifacts in high-magnification micro-CT.

Abstract

Monolithic scintillators are a promising alternative to standard pixelated crystals in positron emission tomography, as they can be more cost-effective, reduce dead space, and capture an unobstructed light distribution, which can be used for depth of interaction estimation. We focus on the improvements seen by using an array of integrated corner reflectors (ICR) machined directly into the entrance face of the monolith, which we previously showed via simulation to improve light collection and narrow the light distribution. In this study, we built a physical prototype of the device using a CNC machining process. We compared this prototype with other monolithic block designs. We show that the ICR monolith with the CNN positioning algorithm has potential for high-resolution imaging with ~1 mm resolution at 12 mm thickness. Using GATE simulations, we constructed a full scanner with the performance of the monolithic blocks and tested the capabilities compared to existing systems. We show the improved spatial resolution and feasibility for a non-cylindrical design for axillary lymph node scanning.

Abstract

Pixelated crystal arrays are the standard in commercial PET scanners. However, these detectors usually lack DOI information, essential to achieve a homogenous spatial resolution along the entire FOV. Yet, studies have been already performed with pixelated detectors with DOI capabilities but at the cost of using extra hardware material and/or crystal assembling. Inspired by semi-monolithic crystal geometries, pseudo-slabs were proposed as an alternative. This geometry consists of an $N \times N$ pixel array optically isolated only in one direction, allowing light crosstalk in the orthogonal one. The N pixels sharing light in this direction form a pseudo-slab. The light sharing within a pseudo-slab is enough to enable DOI retrieval, while the physical separation between pixels confines the light more than in a pure slab geometry, yielding better time resolution.

In this work we evaluated the DOI resolution of a BGO block formed by 8×8 pixels, each measuring around 3×3×15 mm^3. Two different readout configurations were employed and compared. First, all the 64 channels corresponding to the TOFPET2 ASIC channels were digitized. Then, a multiplexing circuit was utilized, reducing the signals to 8+8 by summing rows and columns. The DOI was obtained using neural networks trained on experimental data.The results show a good DOI resolution for both readout configurations, achieving 3.8 ± 1.3 mm with the multiplexing circuit. These results show that pseudo-slabs are suitable for clinical PET scanners with DOI capabilities.

Abstract

High-sensitivity, high-resolution brain-dedicated SPECT systems are critically important for advancing diagnosis and surgical planning in complex neurological disorders such as epilepsy, Parkinson's disease, and Alzheimer's disease. In this paper, we present *SurfaceCam*, a close-proximity multi-pinhole SPECT architecture with a radially adaptable rotating gantry, designed specifically for clinical brain imaging. The system comprises 15 detector-collimator panels distributed across three detector heads in a cylindrical arrangement, operating at a 1:8 minification geometry with a 28 cm bore. Each panel integrates 16 high-performance CZT sensors in a compact 2×8 configuration. The three detector heads translate radially to accommodate varying patient head sizes while maintaining close-proximity geometry, and the rotating gantry enables micro-rotation between acquisitions to facilitate angular super-sampling strategies. Pinholes are organized into groups of four with a twisted geometry, each subtending partial coverage of the 20 cm spherical FOV, while eliminating inter-pinhole projection multiplexing on the detector surface. Analytical comparison against a conventional 1:11 minification compound-eye reference design demonstrates approximately 1.4-fold higher geometric sensitivity and approximately 27% improvement in effective pinhole spatial resolution. The front-end electronics and data acquisition systems have been fully developed and validated, with Monte Carlo simulation studies and experimental phantom validation currently underway.

Abstract

Photon-counting CT (PC-CT) is a powerful spectral imaging technique that identifies materials by counting individual X-ray photons. While direct-conversion systems are entering clinical practice, we are developing a cost-effective, large-area scintillator-based PC-CT system using YGAG:Ce coupled with silicon photomultipliers (SiPMs). PC-CT excels at identifying high-atomic-number elements like gold (Au) by utilizing its K-edge (80.7 keV). Gold nanoparticles (AuNPs) are promising for drug delivery, as their biodistribution can be controlled by particle size, enabling selective tumor accumulation via the enhanced permeability and retention (EPR) effect.

In this study, we evaluated the in vivo biodistribution of AuNPs in tumor-bearing mice using our SiPM-based PC-CT. Two sizes of AuNPs (1.9 nm and 15 nm) were intravenously administered, and their accumulation was quantitatively assessed using multi-energy CT concentration estimation. Results showed distinct size-dependent patterns: 1.9 nm AuNPs exhibited rapid renal clearance and bladder accumulation, while 15 nm AuNPs showed prolonged circulation and significant hepatic accumulation. Tumor accumulation was confirmed for both sizes, demonstrating the potential of our SiPM-based PC-CT for quantitative in vivo nanoparticle imaging.This presentation reports on the
experimental setup, the analysis methods, and the results obtained.

Abstract

X-ray computed tomography (CT) is essential nondestructive internal imaging. Photon-counting computed tomography (PC-CT) acquires X-ray energy information to enable material identification and quantitative density evaluation. Combining PC-CT energy information with magnetic resonance imaging (MRI) data is expected to provide a novel diagnostic approach to visualize inflammation through tissue water fraction estimation. We developed a PC-CT system combining high-speed scintillators (YGAG:Ce) and silicon photomultipliers (SiPMs), specifically utilizing multi-pixel photon counters, MPPCs, which are optical semiconductor devices. This study evaluated healthy and fatty liver rat models (fed a high-fat diet for two or four weeks). Liver fat fractions, estimated from energy-dependent linear attenuation coefficients, showed good agreement with MRI and pathological results. Furthermore, we performed a detailed pathological evaluation focusing on inflammation induced changes in tissue water content. By integrating high reliability MRI fat fraction data with PC-CT data, we improved the estimation accuracy of water content and quantitatively visualized tissue "water-richness" (edema). Increased water proportions in fatty liver groups suggested inflammation progression. These findings demonstrate that PC-CT is highly valuable for quantitative evaluation of liver disease within a multi-modality imaging approach.

Position-, direction- and contrast-dependent measurement of MLEM-reconstructed PET resolution using a 3D-printed cube (#1967)

Santiago Alvarado Orozco[1], Matthijs Sevenois[2], Georg Schramm[1]

[1] KU Leuven, Department of Imaging and Pathology, Leuven, Belgium; [2] UZ Leuven, Division of Nuclear Medicine, Leuven, Belgium

Abstract

The reconstructed spatial resolution of a PET image is determined by both intrinsic scanner properties and the chosen reconstruction algorithm. Standard NEMA measurements use point sources reconstructed with FBP and therefore mainly characterize the scanner. They are thus suboptimal for predicting the resolution of images reconstructed with MLEM and point-spread-function modeling, as is common in clinical practice.

We propose a 3D-printed resolution cube with an off-center inner compartment which, combined with a mid-acquisition phantom flip and a single reconstruction, produces sharp edges at finite (2:1) contrast along three orthogonal directions. Position-, direction- and contrast-dependent edge and line spread functions (ESFs, LSFs) are then extracted using smoothing-spline fits. As a proof of concept, the method is applied to the NeuroExplorer brain PET system at the isocenter and 10 cm off-center, with and without depth-of-interaction (DOI) modeling.

The LSFs are non-Gaussian with pronounced negative side lobes. With DOI, the resolution is approximately 2.5 mm FWHM in all directions at both positions; without DOI it degrades radially to about 4 mm at 10 cm off-center. Notably, differences between finite and infinite contrast are small in most configurations.

The method provides a position-, direction- and contrast-dependent characterization of PET resolution from clinically reconstructed images and complements NEMA point-source values for image quality comparison, harmonization and partial volume correction.

A Clinically Viable, Scalable Implementation of Monte Carlo Scatter Correction for PET/CT (#2119)

Danielle Zeltser[1], Ester Hait-Fraenkel[1], Xuezhu Zhang[2], Michal Edelstein[1], Gali Elkin-Basudo[1], Yaniv Mizrachi[1], Yariv Grobshtein[1]

[1] GE HealthCare, Molecular Imaging, Haifa, Israel; [2] GE HealthCare, Molecular Imaging, Waukesha, USA

Abstract

Monte Carlo scatter correction is well established as a highly accurate approach for scatter estimation in PET/CT imaging. It demonstrates superior robustness compared with model based scatter estimation methods, particularly under extreme variations in activity distribution and in the presence of patient motion, conditions under which model based approaches often produce artifacts. Despite these advantages, Monte Carlo scatter correction is computationally intensive, and does not inherently account for out-of-field scatter. In this work, we address both limitations and propose an implementation suitable for integration into routine clinical workflows. A multi-GPU implementation, as well as parallel processing with efficient data streaming significantly reduce the processing time. To handle out-of-field scatter, we separately handle regions where information about out-of-field distribution is known, and can be used for a highly precise estimation. In regions where out-of-field information is inaccessible, the effect on scatter is approximated by the measured data, while ensuring a smooth transition in which the high-accuracy region governs the final estimate. Our approach is scalable and robust across system designs ranging from a standard axial field-of-view to a long axial field-of-view, each presenting distinct considerations for scatter estimation. We demonstrate the effectiveness of our method using phantom and clinical data.

Evaluation of Motion Correction Methods on the NeuroEXPLORER Using Multi-Tracer Human Data (#2130)

Jiazhen Zhang, Tianyi Zeng, Yifan Hu, Kathryn Fontaine, Tommaso Volpi, Takuya Toyonaga, Richard E. Carson

Yale University, New Haven, USA

Research funding support: U01EB029811.

Abstract

Accurate motion correction is critical for dynamic brain PET, particularly on the high-resolution NeuroEXPLORER (NX), where residual head motion can blur focal targets and bias time-activity curves (TACs). We evaluated multiple motion correction (MC) strategies using 17 multi-tracer human NX PET scans, including no motion correction (NMC), post-reconstruction registration (PRR), registration before attenuation correction (RBA), UMT-based frame-averaged correction (AVG), and UMT-based event-by-event correction (EBE). Performance was assessed using qualitative image comparison and ROI-based residual TAC variability (%SD_{res}) from 20-70 min. All MC methods reduced %SD_{res} compared with NMC. Across all tracers, subjects, and ROIs, EBE achieved the lowest residual variability (1.40 ± 1.27%), followed by PRR (1.79 ± 1.49%), RBA (1.94 ± 1.64%), AVG (2.01 ± 1.63%), and NMC (4.68 ± 4.26%). Poisson noise-floor analysis further showed that residual motion effects were tracer- and count-statistics-dependent. Overall, UMT-based EBE provided the most effective reduction of residual motion effects in dynamic NX brain PET.

SSS Optimised for Monte Carlo Scatter Estimation for PET (#3060)

Antonia Reeves[3,2], SeyedAmir ZamanPour[1], Simon Noe[1], Simon Arridge[4], Kris Thielemans[2,3]

[1] KU Leuven, Department of Imaging and Pathology, Leuven, Belgium; [2] University College London, Institute of Nuclear Medicine and the Hawkes Institute, London, UK; [3] University College London, Department of Medical Physics and Biomedical Engineering, London, UK; [4] University College London, Department of computer science, London, UK

This work was supported by the i4Health Centre for Doctoral Training, UCL and GE Healthcare. Software used in this project is maintained by CCP SyneRBI (UKRI support: EPSRC grant EP/T026693/1 and STFC through the DRI programme).

Abstract

Recent increases in computational power as well as new tools being more readily available have led to increased interest in Monte Carlo scatter estimation. However, Monte Carlo scatter simulation is still computationally expensive. This is exacerbated by the fact that model-based scatter estimation requires multiple iterations of scatter simulation and image reconstruction. We propose to combine the current clinical standard (analytic single scatter simulation and tail-fitting) with Monte Carlo scatter simulation.

Abstract

The spatial resolution of PET imaging is fundamentally limited by the positron range, whose extent depends on both the emission energy of the radionuclide and the electron density of the surrounding medium. In integrated PET/MRI systems, the static magnetic field exerts a Lorentz force on the positrons, confining their trajectories in the transverse plane to the main magnetic field, potentially improving image resolution. Two complementary experiments were performed using a dedicated monolithic-crystal based PET insert operated at 0T and inside a 9.4T MRI: capillary line sources embedded in three tissue-equivalent phantoms of increasing density (EPF, PLA, and Rigid10k resin), and a microDerenzo phantom. Both tests were carried out with three positron emitters (^{18}F, ^{89}Zr, and ^{68}Ga) eventually use in pre-clinical imaging. The results demonstrate that the magnetic field significantly enhances transverse spatial resolution for high-energy positron emitters in medium- and high-density materials, with FWTM reductions of ~60% for ^{68}Ga and ~18% for ^{89}Zr, while the axial direction remains largely unaffected. Rod resolvability improved at 9.4T from 1.5 mm to ~1.0 mm and from 1.2 mm to 0.9 mm for ^{68}Ga and ^{89}Zr, respectively. . These findings highlight the relevance of both positron energy and tissue-equivalent density in determining the magnitude of magnetic-field-induced resolution improvements in preclinical PET/MRI.

LUCID: Model-Free High-Rate Photon Counting (#1041)

Paul Scoullar, Chris Mc Lean

Southern Innovation, Melbourne, Australia

Abstract

Conventional photon-counting systems rely on dead-time models [1], [2] that saturate at high flux, introduce systematic bias, and require per-channel calibration that scales poorly to large pixel arrays [3]. We present LUCID (Linear Unbiased Count-rate from Interval Detection), which estimates photon flux by measuring the silence between pulses rather than counting individual arrivals, eliminating dead-time modelling entirely. The method assumes only that photon arrivals follow a Poisson process — a condition satisfied by all common detector types at constant source output — and requires no detector-specific dead-time model.

For a Poisson arrival process, the memoryless property of the exponential distribution ensures that gaps exceeding a configurable minimum duration θ_{gap} retain the full statistical information about the true rate λ, regardless of pile-up below that threshold. The unbiased estimator $\hat{\lambda} = (N-1)/T_{excess}$ requires only two hardware-accumulated quantities — valid gap count N and cumulative excess gap duration T_{excess} — and a single division. No knowledge of pulse shape, dead-time, or detector material is required. The estimator variance $\mathrm{Var}(\hat{\lambda}) \approx \lambda^2/(N_{total} \cdot \exp(-\lambda\theta_{gap}))$ provides closed-form uncertainty quantification with graceful degradation at extreme rates rather than a hard saturation limit.

LUCID has been validated from Monte Carlo simulation to commercial deployment, with no per-channel calibration. Simulation demonstrates sub-0.3% RMSE per pixel to 100 Mcps and continued accuracy to 300 Mcps. Eliminating count-rate non-linearity directly improves CT number accuracy, beam-hardening correction, and material decomposition fidelity in photon-counting CT. The architecture requires no high-speed ADC and is suited to FPGA, ASIC, or analogue comparator-integrator realisation [4]. We discuss current work extending the framework toward spectral recovery.

Comparison of scintillator and semiconductor based photon counting detectors via a unique, modular, multi-level simulation framework (PC-SIM). (#2811)

Oliver L.P. Pickford Scienti, Dimitra Darambara

Institute of Cancer Research and The Royal Marsden Hospital, Joint Department of Physics, London, UK

This work was funded by the EPSRC in the UK

Abstract

Spectral photon counting is widely seen as a revolution in medical imaging, however applications will be limited by the spectral performance of the x-ray sensor. Primarily these sensors are made of semiconductors such as CdTe, however in recent years there has been growing interest in whether scintillators could be used as an alternative. These materials lack the high energy resolution of the semiconductors, however they are not affected by the extensive low energy tailing seen in small pixelated semiconductor devices. As spectral photon counting is performed with coarse energy bins rather than fine spectral resolution, this raises the question of which factor is more important for spectral fidelity in energy binned tasks: a narrow intrinsic energy resolution (semiconductors) or the absence of charge sharing induced low energy tailing (scintillators)? This work sets out to compare the two sensor types to answer this question. To do this we use a new simulation tool called PC-SIM (Photon Counting Spectral Imaging Model), which is a modular framework, designed for flexible modelling of a range of spectral photon counting scanner designs. We combine this tool with Monte Carlo simulations performed in GATE to quantify the spectral fidelity of scintillator- and semiconductor-based detectors under a range of conditions, including various numbers of energy bins, pixel sizes, and differing beam spectra (polychromatic and monochromatic sources). This presentation will introduce PC-SIM, outlining its design philosophy, module options and how it was used to compare the scintillator and semiconductor systems as fairly as possible. Results will show under what conditions scintillators might provide comparable photon-counting performance compared with the current gold standard of semiconductor based detectors, but at a cheaper price-point. Limitations and assumptions of this work will be discussed, along with implications of the results.

Single Energy Material Decomposition via X-ray Grating Interferometry (#1679)

Longchao Men, Peiyuan Guo, Jincheng Lu, Li Zhang, Zhentian Wang

Tsinghua, Beijing, China

Abstract

We propose single-energy material decomposition (SEMD), a method that achieves quantitative basis material imaging from a single X-ray grating interferometry (XGI) acquisition without dual-energy scans. XGI inherently provides two independent spectra from a single acquisition, yielding the spectral separation required for material decomposition. SEMD is particularly valuable for dark-field CT, enabling material decomposition directly from the existing acquisition without requiring dual-energy hardware, greatly enhancing the clinical utility of these systems. Experimental results demonstrate that SEMD achieves decomposition accuracy comparable to conventional dual-energy material decomposition (DEMD), providing absorption, dark-field, and basis material images simultaneously from a single scan.

Abstract

Photon-counting computed tomography (PC-CT) shows remarkable potential in low-dose spectral imaging by binning X-ray photons into discrete energy windows. This study presents a novel PC-CT system integrating scintillation detectors and multi-voltage threshold (MVT) digitizers, extends its application to 3D *in vivo* spectral imaging, and specifically evaluates the low-dose imaging performance. Validation results show that the system achieves a detection efficiency of 94.78%, a dark count rate of 0.08 cps/pixel, and a peak count rate of 0.85 Mcps/pixel. Dosimetric evaluations at 120 kVp reveal a central $CTDI_{100}$ of 0.15–0.375 mGy, yielding a dose-normalized figure of merit (FOM) nearly tenfold higher than that of conventional micro-CT. Furthermore, *in vivo* experiments validate the system's capability for high-fidelity 3D material decomposition, even under photon-starved conditions. These results substantiate the potential of the YSO/SiPM-based PC-CT system for precise *in vivo* material decomposition at low radiation doses.

Photon-Counting Spectral Dark-Field Micro-CT for Enhanced Tooth Microcrack Detection (#3183)

Qianyue Ma[1,2], Jincheng Lu[1,2], Sheng Peng[1], Yizhou Bai[2], Longchao Men[1], Li Zhang[1], Zhentian Wang[1]

[1] Tsinghua University, Department of Engineering Physics, Beijing, China; [2] Tsinghua University, School of Clinical Medicine, Beijing Tsinghua Changgung Hospital, Beijing, China

Abstract

Conventional absorption-based dental CT often fails to detect early tooth microcracks due to limited resolution and attenuation contrast. While X-ray dark-field imaging is highly sensitive to sub-pixel structures, traditional systems lack spectral capabilities. To address this, our study utilized a photon-counting grating-interferometry micro-CT system to perform energy-resolved CT imaging of an ex vivo human tooth. Using a 4.8 μm Talbot-Lau interferometer and dual-threshold detection (15 and 30 keV), absorption and dark-field signals were acquired across total-energy (TE), low-energy (LE), and high-energy (HE) channels. Results confirm the complementary nature of the two modalities: absorption imaging better differentiates enamel and dentin, whereas dark-field imaging reveals microcracks with significantly higher conspicuity. Regarding spectral performance, although increasing energy leads to higher overall image noise and decreased clarity (LE > TE > HE), microcrack contrast exhibits the exact opposite trend (HE > LE > TE), peaking in the HE channel with the maximum crack contrast. These findings highlight the advantages of photon-counting spectral dark-field micro-CT for highly sensitive dental crack detection.

Abstract

Next-generation X-ray sources, including 4th-generation synchrotrons and Free-Electron Lasers (FELs) such as LCLS-II, deliver photon rates that saturate conventional photon-counting detectors. ePixUHR-100k addresses this gap with a hybrid X-ray imager providing continuous 100 kfps readout with 104 dB dynamic range and single-photon sensitivity down to 2 keV, capturing single photon and > 1000-photon events with low cross-talk. Power-and area-efficient SAR A/D converters distributed across the pixel matrix enable massively parallel digitization, while a charge-integrating front-end with auto-gain switching sustains fluxes beyond 109 photons/s/pixel. Fabricated in a 130 nm CMOS process, the full-reticle 19.4 × 18.0 mm^2 ASIC is bump-bonded to a 144 × 192 pixel Si sensor and achieves 123 e- RMS noise. Validation of a prototype camera system with a 109Cd radioactive source and at the LCLS X-ray FEL confirms state-of-the-art continuous frame-rate and power-efficiency performance among reported X-ray detectors, including SPAD-based designs. Full ASIC architecture, A/D converter characterization, dynamic range evaluation, gain-switching performance, and comparison with state-of-the-art detectors will be presented at the conference. Scalability toward large-area X-ray cameras will also be discussed through tiled 2 × 2 and 2 × 3 ASIC configurations bump-bonded to large-format Si sensors, enabling systems from 0.5 to 16 Mpixels.

Inverse Analysis of Pulse Pile-Up and Charge Sharing in Photon-Counting Detectors (#1582)

Rikuto Sawada[1], Katsuyuki Taguchi[2], Kenji Amaya[1]

[1] Institute of Science Tokyo, Department of Systems and Control Engineering, Otaku, Japan; [2] Johns Hopkins University, Department of Radiology and Radiological Science, Baltimore, USA

Abstract

Photon-counting detectors offer high spatial resolution and energy discrimination for advanced X-ray imaging. However, their performance is limited due to pulse pile-up and charge sharing, which distort the observed current waveforms.

In this study, we propose a Bayesian inverse analysis framework to estimate photon events directly from observed current waveforms. The detector response is modeled by the drift-diffusion equation. Photon events are parameterized by their energy, arrival time, and interaction position. The event parameters are estimated using Bayesian inference. Prior probability distributions of the number of events and interaction depths are incorporated to obtain physically plausible solutions.

Numerical simulation results demonstrated that the proposed method accurately estimated photon events under pulse pile-up and charge sharing conditions. Furthermore, the reconstructed energy spectra showed reduced distortion compared with the conventional method.

Abstract

All components of a first Time-of-flight CT scanner prototype are now assembled at Université de Sherbrooke where both timing and energy measurements enabled to create first line profiles. Previous simulation studies have shown that, by using these measurements, the contribution of scattered photons to an image can be estimated and removed without an using anti-scatter grid. The scanner prototype can now explore and confirm the measurement and scatter correction methods used in simulation studies. The experimental setup is composed of a scintillator coupled to an SiPM readout and a Weerock front end board. This board includes a Radioroc ASIC along with a picoTDC. An FPGA harvest data and send them to a PC for signal processing. From these data, primary and scatter counts in each pixel can be recovered through the use of an iterative deconvolution algorithm. The experiment successfully produced a small photon counting projection image of an ACR phantom and produced time-of-flight distribution measurements for each pixel with around 550~ps FWHM resolution for the full energy spectrum (30 to 120 keV). Scatter correction lead to a contrast resolution improvement of 195\% in the irradiated bone-water region of the phantom. Its accuracy was partially validated with an analytical calculation of the X-ray's penetration through a part of the phantom with a 5.2\% penetration calculated, and a 10.8\% and 5.7\% penetration before and after scatter correction respectively.

Abstract

Accurate attenuation correction (AC) is essential for quantitative PET imaging, but CT-free AC across diverse radiotracers remains challenging. MLAA-derived μ-maps are useful inputs for deep learning-based AC. However, tracer-dependent biodistribution introduces domain shifts that limit the generalizability of models trained only on ^{18}F-FDG. We propose a single-source cross-tracer CT-free AC framework that combines tracer-robust U-Net regression with anchored flow matching. Local Gamma Field augmentation is used during U-Net training to mimic anatomy-preserving regional intensity and contrast variations in MLAA μ-maps, encouraging tracer-independent MLAA-to-CT mapping. The U-Net output is then used as an anchor for an unconditional flow-matching model trained on CT μ-maps, enabling generative refinement from a reliable deterministic estimate. The proposed method achieved the highest PSNR across all evaluated tracers and reduced MLAA noise, tracer-specific artifacts, and U-Net over-smoothing. AC PET analysis showed strong agreement with CT-based AC PET, with regional uptake correlations closest to the identity line. These results demonstrate that the proposed framework enables accurate and structurally faithful μ-map estimation across multiple tracers using only FDG training data.

High-Energy Penetration Correction in Multi-Aperture SPECT Using Aperture–Plate Ray Decomposition (#1606)

Yusheng Li[1], Qian Wang[2], Liuchun He[1], Hongdi Li[1]

[1] United Imaging Healthcare North America, MI, Houston, USA; [2] United Imaging Healthcare, MI, Shanghai, China

Abstract

Multi-aperture single-photon emission computed tomography (SPECT) at ¹³¹I (364 keV) exhibits a detector-wide plate-penetration halo: a 1.8 cm tungsten plate transmits ~4 × 10^{−4} at μ_W = 4.4 cm^{−1}. Prior corrections perform the aperture/plate split at the photon level via effective-radius point-spread function enlargement, or at the system-matrix level via per-ray full-physics tracing; both merge the two components at storage time, inflating memory by one to two orders of magnitude. We propose a storage-agnostic per-ray partition: a topological rule on the source-to-detector intersection list separates the response into a sparse, peaked aperture component A and a slowly varying plate halo B, upstream of any representation choice. The rule is mutually exclusive and jointly exhaustive, so A_{ij} + B_{ij} = C_{ij} holds bit-exactly against the unsplit baseline for any per-ray contribution functional; the plate path length is a closed-form slab chord minus an analytic aperture chord at O(N_{ap}) per ray. On a 34-module multi-aperture SPECT ring (small-aperture configuration), the identity holds bit-exactly across three projection modes (collimator-path, sensitivity, counts) for a centered single-photon source and across every pixel of 34 Jaszczak hot-rod ¹³¹I views, with per-pixel plate intensity ~10^{−4}–10^{−3} of the aperture peak. OSEM correction with a lagged plate estimate will be presented at the conference.

Abstract

Lutetium background radiation in modern PET scanners enables activity- and tracer-independent transmission measurement for attenuation correction (AC) without CT scans. However, quantitative accuracy of attenuation maps (μ-maps) derived from lutetium transmission (Lu-Tx) is limited by low transmission statistics and noisy randoms estimation from delayed coincidences (DE). In this work, we investigate the use of singles-derived randoms (RS) to improve Lu-Tx-based AC for CT-less PET. Emission and Lu-Tx data were acquired simultaneously on the PennPET Explorer, a 142-cm long axial field-of-view (LAFOV) scanner. μ-maps were reconstructed using maximum-likelihood transmission reconstruction with randoms estimated from either delayed coincidences or singles data, then used for attenuation and scatter correction during PET image reconstruction. The methods were evaluated using physical phantoms, including uniform cylinders, a 190-cm pipe phantom, cylinders with non-uniform axial activity distributions, and an image quality (IQ) phantom. Data were subsampled to simulate low-count short clinical scans. RS produced substantially smoother sinograms while maintaining agreement with DE in total randoms counts. Incorporation of RS improved axial uniformity, reduced noise, and mitigated emission contamination-induced bias in μ-maps, particularly under low-count conditions and non-uniform activity distributions. In IQ phantom studies, AC PET images reconstructed using RS demonstrated contrast comparable to CT-AC PET, whereas DE led to reduced contrast and increased bias, especially for short scans. These results demonstrate that RS improves the quantitative accuracy of Lu-Tx-based AC and support the proposed method as a practical pathway towards CT-less PET for both long dynamic imaging and short clinical scans.

Abstract

Correction of random coincidences is required in clinical PET imaging. Several methods have been proposed to estimate their distributions in a PET acquisition and they mostly use singles detection and/or a delayed coincidence window (DCW). We propose a new approach to achieve this task, which uses the differences in arrival times between consecutive single events that are greater than the coincidence window. This approach is thus less susceptible to bias induced by true coincidences and has more statistics than a DCW. As a proof of concept, a first implementation of this approach was compared to the classic methods using simulations from a small-sized PET scanner. The acquisition of four phantoms, each with different challenges in terms of randoms estimation, were simulated over a range of activities. Overall, the proposed method was less biased than the classical methods while also being more precise than DCW.

Quantitative Activities Evaluation of Ac-225 and Daughter Nuclides Using the Alpha-SPECT Mini System (#3094)

Wenbo Zhao[1], Xuhan Luo[1], Ling-Jian Meng[2], Yong Du[1]

[1] Johns Hopkins University School of Medicine, Baltimore, USA; [2] University of Illinois at Urbana and Champaign, Champaign Il, Champaign, USA

This research was funded by National Institutes of Health, grant number S10OD038221. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Abstract

The Alpha-SPECT Mini system integrates SPECT imaging with CT-based attenuation correction, providing a platform for quantifying in vivo distributions of alpha-emitting radiopharmaceuticals and daughter radionuclides. In this study, three Ac-225 filled syringes with different volumes, 0.5, 4.2, and 18.0 mL, respectively, were scanned with Alpha-SPECT Mini. The ground truth activities were[YD1] 26.12 μCi, 21.62 μCi, and 18.80 μCi from the smallest to the largest syringe, respectively. SPECT listmode acquisition was performed for 20 minutes for each syringe, together with an 80 kV CT scan for attenuation correction. SPECT images were reconstructed for the following photopeaks: 100 keV for Ac-225, 218 keV for Fr-221, 440 keV for Bi-213, and 117 keV for Tl-209. Activities of Ac-225 and these daughter radionuclides, were then estimated from SPECT images using CT defined ROIs and compared with ground truth.

The results showed that quantification accuracy varied with the radionuclides and syringe sizes. Fr-221 and Bi-213 showed relatively lower errors (<5%), while Ac-225 and Tl-209 exhibited larger deviations. The higher errors likely due to the low abundance of low energy (100 keV for Ac-225 and 117 keV for Tl-209) photopeaks and interference from downscatter and collimator penetration from high energy photons. Tl-209 also exhibited larger deviations with a size-dependent trend, suggesting sensitivity to source geometry and scatter correction. Overall, the Alpha-SPECT Mini system showed potential for quantitative imaging of Ac-225 and daughter radionuclides. Future work includes further calibration and implementation of scatter correction.

Physics-Driven Methods for Standardizing Radiomics Features in CT Data (#2771)

Huay Din[1], Yijie Yuan[2], Grace H. Kim[3], Michael F. McNitt-Gray[3], Joseph W. Stayman[2], Grace J. Gang[1]

Abstract

Radiomics have demonstrated potential in numerous clinical applications. However, feature variability resulting from different scanner hardware and image processing degrades predictive ability and reduces model generalizability. We present a novel physics-driven framework for radiomics standardization. Assuming a linear, shift-invariant image formation model, we developed an analytical method to remove the dependency of radiomics features classes on known spatial resolution and noise properties. The method consists of two deconvolution operations: deconvolving the system blur from the reconstructed image, then deconvolving the noise probability density function from radiomics feature distributions. This approach is applicable to multiple feature classes. We further developed a workflow to implement this framework on a clinical CT scanner. The method was evaluated on an anthropomorphic lung phantom imaged at five dose levels and reconstructed using eight kernels. Results demonstrate that the standardization method effectively improves the consistency of radiomics features value with those at reference imaging conditions. As expected, standardizing from smoother kernels to sharp kernels is more challenging than the reverse. The proposed standardization method is a promising tool for improving the robustness and generalizability of radiomics models.

Abstract

^{123}I-DaTSCAN is used to aid diagnosis of Parkinsonism. Visual analysis of ^{123}I-DaTSCAN is used in conjunction with patient clinical history and semi-quantification. Specific Binding Ratios (SBR) are commonly estimated for the right and left putamen and caudate using commercially available software. The estimation of uncertainties is not common for this clinical study; however, the benefits of estimating uncertainties have been recognised for other clinical applications. In this work, a method to evaluate the uncertainty associated with SBR is developed using phantom data and then applied to estimate uncertainties for imaging data from a cohort of patients. List mode data was acquired and bootstrapped to create equivalent sinograms. The sinograms were reconstructed and processed using BRASS software to obtain the distribution of SBR and respective standard deviations were estimated. The impact of estimating uncertainties in patient classification is also considered.

For the patient data, the estimated standard uncertainties varied between 2.8 % and 19 %. The correlation of SBR uncertainty with patient classification within the cohort is presented. Initial analysis suggests the patient classification does not change when considering uncertainty, but does provide confidence in the results.

This is the first time that uncertainties on SBR values are used to evaluate impact on patient classification. Future work will include analysing additional patient data to further investigate the impact of uncertainties in patient classification. Analysis to understand if the uncertainties can be reduced is also planned.

Towards Absolute Resolution Characterization in OSEM Reconstructed Images without Ground Truth: Using FBP Reconstructed Images as the Bridge (#2809)

Yifan Hu[1], Liang Guo[2], Tim Mulnix[1], Thibault Marin[1], Richard E. Carson[1,2]

[1] Yale University, Department of Radiology and Biomedical Imaging, New Haven, USA; [2] Yale University, Department of Biomedical Engineering, New Haven, USA

Abstract

Absolute resolution characterization of OSEM-reconstructed images is challenging because the OSEM algorithm is nonlinear and its resolution strongly depends on the activity distribution and the number of iterations. In contrast, the linear FBP algorithm provides a more consistent resolution, albeit with higher noise. In this work, we propose using FBP-reconstructed images as a bridge to estimate the absolute resolution of OSEM images without requiring ground truth. Two FBP-bridge approaches are investigated: an image-domain Gaussian fitting method and a frequency-domain modulation transfer function (MTF) ratio method. Hoffman phantom experimental results show that the Gaussian fitting approach has better agreement with the reference FWHM obtained using the known phantom ground truth. Both methods are further applied to human brain PET scans. This method also allows pixel-wise visualization of spatially variant image resolution. Future work will investigate the effects of noise and FBP filter selection.

Variable Angle Slant-Hole Collimator for Molecular Breast Imaging System (#1035)

Seungjoon Lee[1], Andrew Weisenberger[1], Bradley Patt[2], James Hugg[2]

[1] Thomas Jefferson National Accelerator Facility, Nuclear Physics, Newport News, USA; [2] Smartbreast Corporation, Sherman Oaks, USA

Abstract

A Variable Angle Slant-Hole (VASH) collimator has been developed for integration with the SmartBreast's Eve ClearScan e750 Molecular Breast Imaging (MBI) system, formerly known as the GE Discovery NM750b. This effort builds upon prior success implementing VASH technology in the Dilon 6800 camera platform, where slanted collimator geometries demonstrated improved resolution and lesion detectability in breast imaging applications. The SmartBreast MBI system incor-porates high-resolution cadmium zinc telluride (CZT) detectors, replacing earlier NaI(Tl)-based designs, and thus necessitates a redesigned collimator geometry to fully leverage the intrinsic resolution and detector compactness. The new VASH design incorporates a reduced hole pitch of 1.84 mm, fixed septal thickness of 0.4 mm, and a shortened collimator depth of 13 mm, in contrast to the original lead-based parallel-hole collimator (2.46 mm pitch, 0.4 mm septa, 21 mm depth). These parameters were selected to balance sensitivity and spatial resolution. Ana-lytical calculations indicate that the redesigned VASH achieves comparable or improved resolution and sensitivity performance at clinically relevant object-to-collimator distances up to 60 mm. The first prototype is under construction, with mechanical inte-gration, phantom imaging, and angular performance evaluation scheduled for upcoming testing. The VASH system offers imaging flexibility in clinical MBI and has potential implications for improving detection of lesions at variable depths in dense breast tissue.

Abstract
The performance of gamma detectors for time-of-flight positron emission tomography (TOF-PET) has improved significantly over the last decade. With commercial systems surpassing the 200~ps coincidence time resolution (CTR) barrier, the avenues for improving TOF-PET detector performance become progressively more limited. We report on CHLOE (Cherenkov Light Module), a PET detector readout with high channel density composed of dual ended readout bismuth germanate (BGO) crystals coupled one-to-one to silicon photomultipliers (SiPMs) with the goal of providing a trade-off between 3D detector segmentation, energy resolution, and scalability in an intrinsic radiation-free crystal. The electronics were based on the FastIC+ chip and the complete readout chain, from the front-end to the back-end was customized for this concept.

This work presents the first electronic and detector characterization of the CHLOE readout approach. The noise and dark counts contributions of the system are presented, including measurements of channel dependencies in the response. Energy spectra were obtained for ^{22}Na and ^{133}Ba sources. The work presented in this contribution represents the very first steps towards a full functional characterization of the CHLOE readout.

A 0.32 mm Pitch GAGG Array-Based SPECT Detector (#1596)

Jiahao Xie, Haibo Wang, Jinyi Qi, Simon R. Cherry, Junwei Du

University of California at Davis, Biomedical Engineering, Davis, USA

This work was supported by the NIH R01 EB031961.

Abstract
Multi-tracer preclinical single-photon emission computed tomography (SPECT) enables simultaneous tracking of multiple physiological processes inside organs, requiring detectors with high spatial and energy resolution over a broad energy range. In this study, we developed and evaluated a high-resolution detector comprising a 28 × 28 gadolinium aluminum gallium garnet (GAGG) array (0.32 mm pitch, 2 mm thickness) coupled to a linearly graded silicon photomultiplier (LG-SiPM) using radiation sources with different energies: 55, 122, 202, 307, 511 keV. Flood histograms demonstrated clear separation of crystal elements over a wide energy range from 55 keV to 511 keV.

Furthermore, the detector achieved energy resolutions of 18% at 122 keV and 12% at 511 keV, along with excellent energy linearity across 55–511 keV (R^2 = 0.996). These results demonstrate that the developed detector is a promising candidate for high-resolution small-animal SPECT systems.

Sub-millimeter PET detectors using multiplexed readout with ASIC

(#1718)

Zhiqiang Zhu, Linjun Zhang, Hui Huang, Haonan Li, Yongfeng Yang, **Zheng Liu**

Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China

This work is supported by the National Natural Science Foundation of China (Grant No. 12375358), the National Key Research and Development Program of China (2023YFF0716000), the Shenzhen Science and Technology Program (JCYJ20220531100000001, JCYJ20220818101804009).

Abstract

This study presents a sub-millimeter resolution small-animal PET detector based on a dual-ended readout configuration with highly multiplexed signal processing, targeting applications in compact and MRI-compatible PET insert systems. The detector employs a LYSO crystal array coupled to silicon photomultiplier (SiPM) arrays on both ends. A row-column summation multiplexing scheme is adopted to compress multi-channel SiPM signals into a limited number of position-encoding outputs, while a dedicated multi-channel ASIC (MPT2321) is utilized for signal amplification, timing extraction, and digitization. The multiplexed signals are directly processed by the ASIC without requiring individual channel readout, significantly reducing the number of electronic channels and system complexity, which is particularly beneficial for integration in high-field MRI environments. Experimental results demonstrate that all crystal elements in the 26 × 26 LYSO array can be clearly resolved in the flood histogram. The detector achieves an average energy resolution of 15.3 ± 0.7%, a DOI resolution of 2.56 ± 0.46 mm, and a detector timing resolution (DTR) of 2.40 ± 0.20 ns. The proposed detector design demonstrates that highly multiplexed readout combined with ASIC-based signal processing can effectively reduce system complexity and cost while maintaining good spatial, energy, and DOI performance, making it suitable for high-resolution small-animal PET imaging and compact PET/MRI insert applications.

Performance Evaluation of a Position Sensitive SiPM for Decoding Ultra-Small Crystal Arrays (#1901)

Jianlang Hua, Xiaoqin Zhang, Ming Niu, Hang Yang, RuiPeng Dai, Zheng Gu

Shenzhen Bay Laboratory, Institute of Biomedical Engineering, Shenzhen, China

This work is supported by the National Natural Science Foundation of China (Nos. 12275182 and 62371314), the National Key R&D Program of China (No. 2023YFC2414800), Guangdong Basic and Applied Basic Research Foundation (Nos. 2024A1515012154), the Guangdong Provincial Project (Grant No. 2023TQ07A233), the Major Program of Shenzhen Bay Laboratory (No. C1012530005) and the Shenzhen Bay Laboratory Proof-of Concept Grants (No. C1022430005).

Abstract

We evaluate the spatial decoding capability and energy resolution of a position sensitive SiPM (PS-SiPM, model PSS 11-6060-S, Capital Photonics Technology, China) with an active area of 6.24 mm × 6.24 mm. The PS-SiPM is optically coupled to a checkerboard-pattern scintillator array, which is composed of alternating LYSO and BGO crystals with a 0.38 mm crystal size and a 0.46 mm pitch, arranged in a 28 × 28 array. To compensate for the lower scintillation light yield of BGO, a custom amplifier board with a nominal gain of 16 was incorporated into the readout chain.

Delayed charge integration (DCI) technique was applied for distinguishing LYSO and BGO events based on pulse shape. The average rise and decay time constants were measured 31 ns and 313 ns for BGO, and 22 ns and 60 ns for LYSO, respectively. Using an Anger-logic positioning algorithm, the resulting flood image successfully resolved a 13 × 13 sub-region of the crystal array, with minimal edge decoding difficulty. It highlights the advantage of the PS-SiPM in identifying edge crystals.

Energy resolution was evaluated within a central 9 × 10 crystal pixels to mitigate intrinsic geometric constraints. The 45 LYSO crystals in this region achieved an average energy resolution of 18.52% ± 2.39%, and the 45 interleaved BGO crystals achieved 25.54% ± 2.48%. These results confirm the feasibility of using a PS-SiPM for decoding sub-millimeter crystal array, and provide a performance reference for the implementation of PS-SiPMs in ultra-high-resolution nuclear imaging detectors.

Abstract

We present a physics-constrained joint deconvolution framework for reconstructing photon arrival dynamics. In scintillator-based detectors, measured waveforms arise from the convolutional superposition of stochastic photon detection events, while finite analog signal shaping limits the observable temporal resolution. Mathematical deconvolution approaches implicitly assume continuous photon arrival recovery; however, such formulations are fundamentally ill-posed under band-limited measurements. In this work, we instead represent the latent photon arrival process on a discretized temporal grid as a sampled intensity. Dual-channel timing and energy waveforms are modeled as complementary observations of a shared latent process and jointly inverted using sparsity-constrained optimization. The proposed framework stabilized reconstruction in the presence of bipolar timing responses and temporal smearing, yielding physically consistent photon-train estimates. Joint modeling mitigates ambiguities inherent to single-channel reconstruction and improves robustness in timing extraction under degraded signal conditions. These results establish photon-train reconstruction as a physically grounded representation of detector response and a principled framework for interpreting temporally overlapping signals.

Abstract

Over the past years, significant advances have been achieved in Time-of-Flight Positron Emission Tomography (ToF-PET) systems, reaching coincidence time resolution (CTR) values below 100 ps. However, this performance has been demonstrated in small-scale detectors using short scintillation crystals, which favor timing performance at the expense of detection efficiency, and high-power electronics. In contrast, realistic system designs require scintillator crystals with thicknesses of >=10 mm to ensure high detection efficiency. Pushing the CTR limits in large crystals remains challenging due to optical photon transport effects and depth-of-interaction (DOI) uncertainties.

For this purpose, we investigate a dual-ended read out detector based on a 3x3x20 mm^3 LYSO:Ce,Ca crystal against a 2x2x3 mm^3 Fast-LGSO crystal used as a timing reference. The read out was performed with the FastIC+, a custom application-specific integrated circuit (ASIC) multi-channel front-end with on-chip digitization. This ASIC is specifically design for fast-timing applications and optimized for the read out of high-gain photodetectors such as silicon photomultipliers (SiPMs).

In this work, we apply an energy-based DOI correction method to improve the CTR performance of thick-crystal detectors. Using a dual-ended detector based on a 3x3x20 mm^3 LYSO:Ce,Ca crystal coupled to 4x4 mm^2 SiPMs and measured against a 2x2x3 mm^3 Fast-LGSO reference detector coupled to a 3x3 mm^2 SiPM, we achieve a CTR of (135 +/- 1) ps without DOI correction. After applying the correction, the CTR improves down to (110 +/- 1) ps. These results obtained for thick crystals opens a clear path toward sub-100 ps performance in realistic scanner configurations.

Deep Learning Depth-of-Interaction Estimation from Full-Waveform Single-Ended PET Readout: Spatial Resolution Limits (#2163)

Marcus Luck[1], Luca Macchiarulo[1], Christopher Chock[1], Isar Mostafanezhad[1], Hamid Sabet[2]

[1] Nalu Scientific, LLC, honolulu, USA; [2] Massachusetts General Hospital & Harvard Medical School, Radiology, Boston, USA

Abstract

Depth-of-interaction (DOI) estimation is a bottleneck in next-generation PET, contributing to parallax error and degraded timing resolution. Existing solutions using double-sided readout, phoswich, monolithic, or layered crystals require substantial modifications to the readout or detector stack. As part of the development of the SymPET waveform-digitizing readout ASIC, we investigate whether photon arrival-time waveforms alone carry sufficient information to recover DOI without auxiliary sensing. Using DETECT2000 Monte Carlo simulations of 2×2 mm LYSO rods coupled one-to-one to SiPMs, we compare polished and unpolished surface treatments at 12 and 20 mm lengths and train a hybrid 1D CNN-Transformer regressor on 50 ps-binned photon arrival-time histograms. Unpolished surfaces yield lower per-Z MAE and residual std than polished. Bundled high-SNR events reach 0.18 mm worst-per-Z MAE, while single-event MAE is 2.53 mm. Showing the information is present in the waveform, closing this SNR gap is the open problem. (Preliminary results.)

Abstract

This study is aimed at the development of a dynamic micro imaging technique based on nuclear medicine methods. Single-cell resolution imaging is strongly required to study the properties and mechanisms of cells for

improved efficiency of drug development. Conventional nuclear medicine imaging techniques are not suitable for this purpose due to their limited spatial resolution. Autoradiography works in terms of spatial resolution, but it cannot obtain dynamic images. Therefore, we are developing a micro radioisotope (RI) imaging system to realize dynamic cell observation. This system consists of a CCD camera and a scintillator plate. Instead of the eutectic scintillator that we introduced in the last IEEE MIC conference, which had non-uniformity and insensitive region issues for this purpose, in this study we use an optical-guiding crystal scintillator (OCS) which has a 10 μm fiber structure.We developed a prototype of the system using the OCS plate, an objective lens (x4) and an CCD camera (C9100-23B). The length, width and thickness of the OCS plate were approximately 2 mm × 5 mm and ~160 μm, respectively. The diameters of the cores in the OCS plate were ~10 μm. In evaluations, a slide chamber was filled with FDG solution, covered with an 8 μm thick polyimide film and then directly put on the OCS plate. The scintillation lights generated by irradiation of positrons from a FDG were detected with the CCD camera through an objective lens. As a result, optical and scintillation images were obtained with the developed system using the OCS. In addition, using half-life measurements, we confirmed the obtained scintillation images were exactly derived from the interactions between the positrons of the F-18 and the OCS. In the next step, we will evaluate performance of the prototype micro RI cell imaging system in measurements with actual cell samples.

This work is sponsored by BMFTR, contract numbers 13GW0609A, 13GW0609B, 13GW0621A and 13GW0621B. Part of this work was performed in the framework of Crystal Clear Collaboration.

Abstract
The S-PET project is developing a high-resolution positron emission tomography detector module intended for simultaneous brain positron emission tomography / magnetic resonance imaging. The detector needs to feature good position resolution including depth-of-interaction capabilities as well as good timing resolution. A core challenge is the limited space for electronics. The detector integrates 12×12 or even 16×12 SiPMs with one 64-channel TOFPET2 ASIC, necessitating efficient channel compression schemes without additional elements that leverage light-sharing for event positioning. Crucial optimization parameters for detector performance include the crystal topology and a matching compression scheme. This work evaluates Time-of-Flight and Depth-of-Interaction performance across multiple compression schemes and crystal topologies: continuous slabs, pseudoslabs, and pixelated arrays with a light guide coupled to the face opposite the photosensitive detector. This study utilizes

modular development boards, that allow for quick swapping of the compression scheme without reattaching the crystal array, and the first full-scale sensor tile with one of these compression schemes, the Hyperion Visor HD. Preliminary results with a 48×48 mm^2 BrainPET 7T crystal array on the latter show planar resolutions with Mean Absolute Error below 1.5 mm. First tests without compression schemes on a development board with 16×16 mm^2 crystal arrays (2 mm and 4 mm pixel size) with light guide on top show good timing (Coincidence Time Resolution of 235 ps) and Depth-of-Interaction resolution (Mean Absolute Error <1.5 mm). While these preliminary results are promising, the comprehensive evaluations utilizing several crystal topologies combined with the different compression schemes will be presented at the conference.

An ultralow-afterglow γ-camera prototype for hybrid interventional X-ray and scintigraphy imaging (#2497)

Marc Snoeyink[1], Lukas Schröder[1], Peter Menge[2], Dennis R. Schaart[1]

[1] *TU Delft, TNW/RST, Delft, Netherlands;* [2] *Luxium Solutions, Hiram, USA*

Abstract
Radioembolization is widely used for treating cancer, e.g. in the liver. The procedure currently consists of two sessions, one for imaging and one for treatment, typically several weeks apart. Cost-effectiveness, accuracy of treatment, and patient experience could all be improved if both steps could be combined into a single interventional session. A multimodal detector that integrates an X-ray flat panel with a γ-camera would make this possible, by capturing anatomical information and dose distribution at the same time. During X-ray imaging, however, a portion of the radiation passes through the flat panel and blinds the γ-camera. In principle, γ-photons could be detected in between X-ray pulses, but the high afterglow of the currently used NaI(Tl) scintillator interferes with the γ-photon signals. To overcome this, we explore the use of a low-afterglow scintillator in a pixelated γ-camera design. Reducing afterglow facilitates γ-detection shortly after X-ray exposure. Pixelation further increases the γ-photon signal intensity relative to the afterglow background. The pixels are coupled one-to-one to silicon photomultipliers (SiPM). Here, we characterize a prototype module based on NaI(Tl,Sr,Y), which we previously showed to have a low afterglow of 500ppm at 100ms. The module is hermetically sealed to protect the hygroscopic scintillator and comprises 6 x 6 crystals of 3.75 x 3.75mm x 9mm, separated by 0.25mm thick Teflon reflectors. The central 4 x 4 pixels are coupled to a 4 x 4 SiPM array. The 20 inactive outer pixels ensure equal inter-crystal scatter conditions for all active pixels. Event positioning is based on a winner-takes-all algorithm. The performance of the prototype detector is evaluated by measuring Am-241, Ce-141 and Co-57 pulse-height spectra of all active pixels, with and without simultaneous exposure to a pulsed X-ray source.

Abstract

The dominant cost driver in total-body positron emission tomography (TBPET) systems is the scintillator material. Current commercial scanners rely on LYSO crystals, which are costly and depend on geographically concentrated rare-earth supply chains. CRYSP proposes an alternative TBPET design based on large monolithic pure cesium iodide (CsI) crystals operated at cryogenic temperatures (~100 K). At these temperatures, CsI achieves a light yield of ~10^5 photons/MeV, yielding an energy resolution below 7% at 511 keV. The monolithic geometry provides inherent depth-of-interaction (DOI) capability, enabling millimeter-scale spatial resolution in all three dimensions and minimizing parallax error. These properties compensate for the lower sensitivity and absence of time-of-flight information, allowing image quality competitive with state-of-the-art TBPET scanners at substantially reduced cost. The slow decay time of cryogenic CsI (~800 ns) renders conventional readout electronics unsuitable; a front-end based on the CAEN CITIROC ASIC, providing pulse-height analysis well suited for slow scintillators, was adopted instead for the prototype. Event position reconstruction employs both analytic methods and a deep-learning algorithm trained on Geant4 simulations, achieving millimeter-scale resolution including DOI in Monte Carlo studies. As a first proof-of-concept, a small-scale PET scanner comprising 18 monolithic CsI(Tl) crystals operating at room temperature is under development, providing hands-on experience with the full acquisition and reconstruction chain before advancing to a cryogenic prototype.

Abstract

The precision to which the arrival time of 511 keV photons are able to be known directly affects the signal-to-noise-ratio (SNR) for reconstructed images in time-of-flight positron emission tomography (TOF-PET). Currently, significant research is ongoing to push the full-width-half-maximum (FWHM) coincidence time resolution (CTR) for TOF-PET systems well below 100 ps towards the few-10's-of-ps regime. In this work, we designed an application specific integrated circuit (ASIC) in a commercial 65nm CMOS process to translate ultra-fast timing performance currently demonstrated in state-of-the-art bench-top measurements into a fully integrated scalable topology for large scale time-of-flight positron emission tomography (TOF- PET) systems. We targeted a scalable, low-noise, ultra-fast silicon photomultiplier (SiPM) analog front-end that maintains excellent SNR for single photon response while achieving ≤35 ps FWHM electronic noise jitter for single photon detection with 4x4 mm^2 Broadcom AFBR-S4N44P014M Near-ultraviolet metal-trench SiPMs. This "analog" chip uses low-voltage differential signaling (LVDS) transmitters to drive discriminator data to an external time-to-digital converter (TDC). We present evaluation of achievable single photon time resolution and CTR with the first prototype test chip.

A Dual-Ended Readout PET Detector Module With 0.75 mm Pitch LYSO Arrays for High-Resolution Small-Animal Imaging (#2714)

Shihan Yang, Xianchao Huang, Xiaorou Han, Hang Yuan, Hanri Liao, Long Wei, Zhiming Zhang

Chinese Academy of Sciences, Institute of High Energy Physics, Beijing, China

This work was supported by the National Key R&D Program of China (Grant No. 2023YFF0716000).

Abstract

We present a high-resolution PET detector module with fine-pitch crystals and dual-ended readout for small-animal imaging. The detector employs a 28 × 28 LYSO crystal array with a pixel size of 0.75 mm × 0.75 mm × 15 mm, separated by 0.08 mm $BaSO_4$ reflector layers and read out at both ends by SiPM arrays. Experimental results demonstrated clear crystal separation with a corrected depth-of-interaction (DOI) resolution of 1.59 mm (FWHM) and an energy resolution of 14.9% in the selected 1/4 detector region. These results indicate that dual-ended readout can effectively improve DOI resolution in fine-pitch crystal arrays while preserving crystal separation, demonstrating the feasibility of fine-pitch dual-ended PET detectors for high-resolution small-animal PET imaging.

Abstract

Mechanical collimators in SPECT introduce a fundamental sensitivity-resolution trade-off that becomes critical in targeted radionuclide therapy (TRT) imaging, where administered activities are low. We explore a collimator-free detector concept based on an 18x18 pixelated GAGG scintillator array in which collimation is achieved through staggering, that is, height offsets between neighboring pixels that produce characteristic shadow patterns in the resulting flood map. Three configurations are evaluated: a flat array (stagger-0), a single-pixel checkerboard (stagger-1), and a 3x3-block checkerboard (stagger-3). For each geometry, OpenGATE 10 Monte Carlo simulations of a 140 keV point source were performed at 400 positions on a fixed-height plane. The resulting flood maps were used to train a 2D convolutional neural network that regresses the source coordinates. Evaluated on 40 test positions, the 3D root-mean-square error of the neural network decreases with increasing staggering degree, from 0.44 mm (stagger-0) to 0.40 mm (stagger-1) and 0.34 mm (stagger-3), a 23% reduction that supports staggering as a promising strategy for collimator-free source localization.

Development and Experimental Characterization of a Fine-Pitch CZT SPECT Detector Head with Simulation-Guided Matched-Pixel Collimator Selection (#3083)

Zhiyong Song[2], Rui Wang[1], Pengyu Ke[2], Xu Chen[2], Zifan Hao[2], Jingzhe Gong[3], Xinyu Lv[2], Shaohui An[2]

Abstract

A fine-pitch CZT detector-head prototype was assembled and experimentally characterized for SPECT imaging. The head consists of a 5 × 10 tiled array of CZT modules, each containing 16 × 16 anodes with 1.45 mm pixels and a 1.6 mm pitch. The prototype achieved a global energy resolution of 4.8% at 140 keV. The intrinsic integral and differential uniformities were 0.56% and 0.44%, respectively. To exploit the fine intrinsic spatial sampling of the CZT detector, a fast ray-tracing Monte Carlo framework was used to explore dual-layer 1H/4HMPD matched-pixel collimator candidates and to compare them with the 1HL30.5 reference design, defined as a one-hole-per-pixel collimator with a 30.5 mm hole length, under prototype-constrained geometric and mechanical conditions. A representative dual-layer candidate showed an alternative main-lobe sensitivity–resolution trade-off, but GATE point-source simulations revealed more pronounced non-Gaussian tails than the 1HMPD reference. Therefore, the 1HL30.5 configuration was retained as the near-term practical collimator design. GATE-simulated Derenzo phantom reconstruction of this configuration showed that 5 mm hot rods were visually distinguishable at 10M and 5M total projection counts. These results support the feasibility of the fine-pitch CZT detector-head prototype and justify retaining 1HL30.5 for subsequent experimental phantom validation.

Abstract

This study investigates the influence of magnetic fields on F-18 and Ga-68 positrons and how they affect image quality metrics in tissue-equivalent phantoms relevant to PET/MR imaging. To this end, we performed Monte Carlo simulations using the PENELOPE code. Since the main PENELOPE routine penmain.f does not account for the influence of electromagnetic fields on radiation transport in matter, a modified version of the penfield.f module was used instead. Simulations were carried out in four representative media (lung, soft tissue, water, and cortical bone) and in NEMA-like image quality phantoms to assess the effect of uniform magnetic fields of 0, 3, and 9 T. We simulated positron point sources at the center of a 10 cm-radius spherical phantom of homogeneous materials and in a set of three image-quality phantoms to evaluate specific image-quality parameters: spill-over ratio, recovery coefficient, and lesion detectability, as in a previous experimental study. The results indicate that positron range significantly affects recovery coefficients and spill-over ratios, particularly for high-energy positron emitters in low-density tissues. In the recovery-coefficient phantom, when the cylinder separation distance is smaller than the positron range, a slight overestimation of the recovery coefficients is observed due to contributions from adjacent cylinders. The magnetic field reduces these effects in the direction perpendicular to the magnetic field lines, leading to improved spatial resolution and quantitative accuracy. These findings represent the maximum image quality that can be achieved under ideal conditions in a PET system in the presence of uniform magnetic fields and provide a physical basis for the development of positron-range correction methods in PET/MR imaging.

Abstract

To improve the detectability of small lesions and early metastases, we are developing a breast PET insert that operates in conjunction with a whole-body (WB) PET/MRI scanner. We implemented a joint reconstruction framework with attenuation correction that explicitly accounts for the different coincidence types from the insert and the WB-PET, aiming to improve spatial resolution inside the insert field of view (iFOV), as well as outside. Performance was evaluated using Monte Carlo simulations of an anthropomorphic phantom with lesions of 4, 8, and 12 mm diameter and contrast ratios of 4:1 and 8:1 relative to the breast background. Lesions were placed at clinically relevant locations, including within the breast, as well as in axillary and parasternal lymph nodes. Compared to WB-PET alone, the inclusion of all coincidence types improved lesion conspicuity, particularly for small (4–8 mm) and low-contrast lesions. Within the iFOV, breast lesions show increases in contrast recovery coefficent (CRC) of up to 16.4% (4 mm, 8:1) and 16.9% (8 mm, 4:1), with 4-mm lesions becoming resolvable. Similar trends were observed for axillary lymph nodes, with CRC increases of up to 11.9% (8 mm, 4:1). Future work will extend this study beyond the idealized 511 keV case to more realistic energy windows with finite energy resolution and higher scatter contribution, as well as incorporate spatially variant point spread function modeling and scatter correction into the reconstruction framework.

Proposal of an L-shaped Dual-detector Multi-pinhole Myocardial SPECT System Using a CNN (#1523)

Takumi Akatsuka[1], Koichi Ogawa[2]

[1] Hosei University, Applied Informatics, Graduate School of Science and Engineering, Koganei, Japan; [2] Hosei University, Applied Informatics, Faculty of Science and Engineering, Koganei, Japan

Abstract

Dedicated cardiac semiconductor SPECT systems enable short acquisition times owing to their high sensitivity; however, artifacts may occur depending on patient body habitus, and quantitative reconstruction images cannot be obtained because attenuation correction using X-ray CT images (μ-maps) is not available. In this study, we propose a novel SPECT system in which two gamma cameras equipped with NaI scintillators are arranged in an L-shaped configuration, allowing data acquisition while keeping the detectors stationary, and achieving attenuation, scatter, statistical noise and collimator aperture correction using a convolutional neural network (CNN). To improve sensitivity, 44 multi-pinhole collimators were employed, and projection images were acquired in an overlapped manner and accurately separated using the CNN. A U-Net++ architecture was adopted to construct a unified framework for overlap separation of projection data, statistical noise reduction, aperture correction and attenuation/scatter correction without requiring μ-maps. Image reconstruction was performed using the ML-EM algorithm, and image quality was evaluated using the normalized mean squared error (NMSE) of the polar map. As a result, approximately uniform image reconstruction was achieved without using μ-maps, and the NMSE was 0.0402, demonstrating the effectiveness of the proposed method.

This work was supported by IEEE Nuclear and Plasma Sciences Society (NPSS).

Abstract

Accurate physics-based simulations are essential for assessing and validating scanner geometries and reconstruction algorithms. EduPET is an NPSS-supported educational PET technology demonstrator. This work introduces the Educational PET SIMulation system (EduPETSIM), an integrated web-based framework designed for educational purposes to streamline the entire PET workflow. The platform unites an OpenGATE-based simulation engine, a custom coincidence sorter, and an image reconstruction module within a unified environment. A primary novel contribution of this framework is the integration of a Conditional Wasserstein Generative Adversarial Network (cWGAN) to facilitate rapid source modeling, which significantly reduces the computational overhead associated with traditional particle transport simulation. Current developments focus on fine-tuning the cWGAN model for a ^{22}Na source within the two-detector EduPET system, with the completed model available for the upcoming IEEE NPSS schools on medical imaging.

Accelerating Monte Carlo Light Transport in Turbid Media with an Analytically Invertible Simplified Phase Function (#1704)

Aristotelis-Nikolaos Rapsomanikis[1,2], Mina-Ermioni Tomazinaki[1], Efstathios Stiliaris[1,3]

[1] National and Kapodistrian University of Athens, Department of Physics, Athens, Greece; [2] University of West Attica, Athens, Greece; [3] Institute of Accelerating Systems & Applications (IASA), Athens, Greece

Abstract

Modeling light scattering in biological media requires balancing the accuracy of Mie theory with the speed of simplified phase functions. We propose a new phase function that replaces the standard *cos(θ)* term with a quadratic θ^2 relationship, significantly improving large-angle fidelity compared to the Henyey-Greenstein (HG) model. A key advantage is the function's analytical invertibility, enabling direct Inverse Transform Sampling that accelerates Monte Carlo simulations by bypassing transcendental computations. Mathematical consistency is validated against the stochastic Rejection Method for various tissues. Transport simulations using the PhoSim package demonstrate enhanced spatial accuracy and closer alignment with the Mie ground truth, offering a high-speed framework for real-time IR tomography and Time-Resolved Optical Tomography.

Fast On-the-Fly System Matrix Computation for Broad-Energy Multi-Pinhole SPECT (#1808)

Bo Gao, Beien Wang, Feng Zhou, Liuchun He, Yun Dong

United Imaging Healthcare, Molecular Imaging Business Unit, Shanghai, China

Abstract

We present a GPU-accelerated system matrix computation method for multi-pinhole SPECT based on spatial modeling of position-dependent point spread functions (PSFs). Sparse Monte Carlo-generated PSFs are fitted with an anisotropic Gaussian model, and the resulting parameters are expressed as geometry-dependent functions to enable estimation of voxel-dependent responses at unmeasured locations. Implemented in CUDA for forward and

backprojection, the method supports on-the-fly iterative reconstruction without storage of a fully precomputed system matrix. This approach was evaluated using Derenzo phantoms and NEMA image quality phantoms filled with isotopes whose emitted photon energies range from 140 to 440 keV, demonstrating its potential for efficient multi-isotope and theranostic SPECT imaging.

Abstract
This work presents a Monte Carlo based performance evaluation of a dual-panel PET&SPECT trimodal imaging system, in terms of spatial resolution, system sensitivity, and count rate performance following the NEMA NU 2-2018 standard. Spatial resolution measurements yield an average value of 1.01 mm for PET and 11.1 mm for SPECT. The SPECT sensitivity with a 700 mm length line source is 101.5 cps/MBq at the center of the field of view (axial offset z = 0 cm) and 103.0 cps/MBq at z = 10 cm. When using a 350 mm line source, SPECT sensitivity increases to 152.1 cps/MBq at z = 0 cm and 129.1 cps/MBq at z = 10 cm. The PET sensitivity measured with a 700 mm length line source achieves 43.4 cps/kBq at z = 0 cm and 43.5 cps/kBq at z = 10 cm. The PET peak noise equivalent count rate reaches 131.5 kcps at 193 MBq in standalone acquisition mode, and decreases under simultaneous PET&SPECT acquisition due to elevated dead time induced by SPECT detections. These results validate the overall system design, quantify the interference between PET and SPECT detections, and provide a foundation for further optimization toward clinical trimodal imaging applications.

Abstract

Advanced detector designs employing multi-layer crystal configurations and multiplexed readouts introduce complex light transport and inter-crystal scatter effects. These result in position-dependent differences in energy response and crystal identification that are difficult to reproduce using idealized simulations. We present an experimentally calibrated GATE simulation framework for a dual-layer depth-of-interaction capable detector developed for a dedicated breast PET/MRI insert. The detector block consists of a 10×10 bottom LSO crystal array (1.5×1.5×9.81 mm³) and a 9×9 top array (1.5×1.5×5.19 mm³). Simulations were performed using GATE v9.4.1 for two geometries and compared against experimental measurements. A reference configuration of 18 detector modules in a 100 mm ring was used to derive crystal-specific correction factors, then applied to the same 18 modules in a 178 mm ring representing the breast insert geometry. Measurements were acquired using a centered Na-22 point source for three energy windows (250–760 keV, 511±50 keV, and 430–610 keV) with experimentally informed coincidence timing resolutions. The uncorrected simulations systematically overestimated experimental coincidence count rates, with the largest deviations at edge and corner crystals of the bottom layer. Prior to calibration, mean absolute deviations for the 178 mm geometry were 37.1%, 38.0%, and 43.0%; following calibration, deviations were reduced to 9.3%, 8.4%, and 8.8%. Experimental detector blocks additionally showed substantially larger crystal-to-crystal variations in energy resolution (top: 12.5±1.1%, bottom: 11.0±1.2%) compared with the fixed simulated values, indicating complex optical transport and detector-specific effects are not yet fully reproduced in the current model.

Abstract

Accurate quantification in preclinical PET remains a fundamental challenge due to the spatial resolution constraints inherent to small-animal imaging, where partial volume effects compromise biodistribution and dosimetry estimations in monoclonal antibody-based radiopharmaceuticals. Here, we present the first integrated digital-twin framework for immuno-PET quantification in preclinical imaging developed around a validated Monte Carlo model of the Bruker (BioSpec 3T) PET/MRI scanner implemented using the SimPET platform — which integrates the SimSET Monte Carlo engine and STIR reconstruction software — and validated following the NEMA NU 4-2008 standard. This validated model was then combined with physical and digital rodent phantoms to assess a highly accurate immuno-PET quantification pipeline. Scanner validation showed a good agreement between simulated and experimental data, with underestimation below 5%. On the other hand, quantification of a representative immuno-PET biodistribution using the Bio-Rat phantom revealed underestimations below 20% across most organs, consistent with partial volume effects at this spatial resolution.

This framework establishes a reproducible strategy to characterize and correct quantification biases in preclinical PET, with direct impact on the translational development of radiopharmaceuticals.

Abstract

The development of portable, low-field MRI systems is currently limited by the computational complexity of optimizing high-density permanent magnet arrays. While traditional Halbach cylinders offer a baseline for transverse fields, achieving medical-grade homogeneity in non-standard, compact geometries remains prohibitive using conventional loop-based physics. This work introduces an ultra-vectorized "Gen-Tensor" engine that revolutionizes the magnet design process by replacing iterative loops with 4D broadcasting and tensor evolution. By parameterizing 300 discrete magnets into a multiple of 2,100-variable generative DNA block (encompassing 3D position, 3-axis rotation, and activation masks), the framework enables the autonomous synthesis of inherently shimmed, multi-layered topologies.

A significant breakthrough of this study is the discovery of a non-standard Cassinian oval architecture that achieves a field magnitude nearly double that of traditional circular cylindrical benchmarks while maintaining high directional purity of the field. This 100% increase in field strength is achieved without an increase in the magnet budget, utilizing the algorithm's ability to exploit non-linear flux-path efficiencies and dynamic compaction. The optimization employs a dual-stage differential evolution protocol, transitioning from a high-entropy exploration phase to a low-mutation precision shimming phase.The resulting parallel flux streamlines, and high directional purity demonstrate a robust pathway for the realization of high-signal, portable MRI systems. This technology is specifically designed for side-by-side operation with existing PET systems in radiologically controlled environments, offering a computationally efficient solution for next-generation point-of-care molecular imaging without the need for intensive post-fabrication shimming.

Design of SSLE-PET with GATE Simulation Towards Sub-Second Dynamic Mouse Imaging (#2309)

Han Gyu Kang[1], Hideaki Tashima[1], Toshiaki Sakai[2], Taiga Yamaya[1]

Abstract

Last year, we developed an ultrasensitive preclinical positron emission tomography (PET) scanner with 4-layer depth-of-interaction (DOI) detectors, thereby allowing sub-second dynamic imaging of a rat. However, the crystal pitch and DOI bins were 2.8 mm and 7.5 mm, which hampered mouse imaging. On the other hand, assembling smaller crystals remains technically challenging. In this study, we designed a novel preclinical PET scanner that uses a sub-surface laser engraving (SSLE) technique to fabricate the finely pixelized crystal elements, and we call it the SSLE-PET. The SSLE-PET consists of 12 DOI detectors, each of which has tapered LYSO crystals with a thickness of 20 mm. The LYSO crystals were pixelized by SSLE, providing fine crystal pitches (top=1.0 mm, bottom=1.6 mm) and 2.5 mm DOI bins. We used GATE simulation to investigate the effects of inner diameter (i.e. detector gap) and axial coverage on the performance of the SSLE-PET. To evaluate spatial resolution and sensitivity, a NEMA ^{22}Na source was used. For imaging performance evaluation, a resolution phantom was used. The GATE output was reconstructed by using a filtered back projection algorithm without any gap filling method. An energy window of 400-600 keV was used. The spatial resolution (1.27 mm) and resolvable rod diameter (1.0 mm) were not affected by the inner diameter. However, gap artifacts appeared for an inner diameter of 70 mm. Hence, an inner diameter of 65 mm would be the best choice to avoid any mechanical collision between detectors, while maintaining the image quality. With an axial coverage of 88 mm, sub-second PET imaging was demonstrated. As a next step, we plan to develop a prototype SSLE-PET scanner.

Abstract

Real-time monitoring in Boron Neutron Capture Therapy (BNCT) exploiting the 478 keV gamma rays emitted by the neutron capture reaction, remains a major challenge due to the intense background present in the irradiation room during treatment. To date, no clinically established system is available, and the choice between SPECT and Compton camera approaches remains an open and highly relevant question.

Here, we present a Monte Carlo (MC) comparison study between a previously developed BNCT-SPECT detector and a LaBr3-based Compton camera for 478 keV prompt-gamma detection.

The goal is to assess the capability of Compton cameras to exploit electronic collimation and directionality for background rejection, thereby improving the signal-to-background ratio (SBR) with respect to SPECT. The results confirm that, in the absence of shielding, SPECT detection is severely dominated by room-induced background. For a vial containing 1000 ppm of ^{10}B irradiated with a thermal neutron flux of 3×10^6 n cm^{-2} s^{-1}, the SPECT configuration yielded an SBR of only 0.009, while the Compton camera achieved an SBR of 3.2. These findings suggest that a Compton camera-based system may represent a promising strategy to address one of the main limitations of BNCT-SPECT systems towards clinical applicability. However, the choice between the two approaches remains challenging, since properly shielded SPECT configurations can still provide high SBR values, while clinically relevant neutron fluences may increase the single-interaction rate in Compton cameras, making true-coincidence identification more demanding and possibly requiring dedicated shielding as well.
